Determining the Consistency of Resolved Triplets and Fan Triplets

JESPER JANSSON,1 ANDRZEJ LINGAS,2 RAMESH RAJABY,3 and WING-KIN SUNG3,4

ABSTRACT

The $R^+ - F^- \text{C}onsistency$ problem takes as input two sets $R^+$ and $R^-$ of resolved triplets and two sets $F^+$ and $F^-$ of fan triplets, and asks for a distinctly leaf-labeled tree that contains all elements in $R^+ \cup F^+$ and no elements in $R^- \cup F^-$ as embedded subtrees, if such a tree exists. This article presents a detailed characterization of how the computational complexity of the problem changes under various restrictions. Our main result is an efficient algorithm for dense inputs satisfying $R^- = \emptyset$ whose running time is linear in the size of the input and therefore optimal.

Keywords: computational complexity, phylogenetic tree, rooted triplets consistency, tree algorithm.

1. INTRODUCTION

PHYLOGENETIC TREES HAVE BEEN USED BY BIOLOGISTS for more than 150 years to describe evolutionary history. In the last 50 years, many methods for systematically reconstructing phylogenetic trees from different kinds of data have been proposed (Felsenstein, 2004; Sung, 2010). In general, inferring a reliable phylogenetic tree is a time-consuming task for large data sets, but the supertree approach (Bininda-Emonds, 2004; Bininda-Emonds et al., 2007) may in many cases provide a reasonable compromise between accuracy and computational efficiency by way of divide-and-conquer: first, infer a set of trees for small, overlapping subsets of the species using a computationally expensive method such as maximum likelihood (Felsenstein, 2004; Chor et al., 2007) and then merge all the small trees into one big tree with some combinatorial algorithm.

In this context, the fundamental problem of determining if a given set of resolved triplets (rooted, binary phylogenetic trees with exactly three leaf labels each) can be combined without conflicts and if so, constructing such a tree, can be solved with a polynomial-time algorithm named BUILD, invented by Aho et al. (1981). BUILD has been extended in various ways (Constantinescu and Sankoff, 1995; Ng and Wormald, 1996; Semple, 2003; Semple et al., 2004; Willson, 2004; He et al., 2006; Jansson et al., 2006, 2010; Sung, 2010).
CONSISTENCY OF RESOLVED TRIPLETS AND FAN TRIPLETS

2012; Snir and Rao, 2006; Guillemot et al., 2011; Huber et al., 2017), for example, to also allow fan triplets (rooted, nonbinary phylogenetic trees with three leaf labels each) or forbidden resolved triplets in the input. It has also been adapted to related optimization problems where the input may contain errors and the objective is to find a tree that satisfies as much of the input as possible; for details, see Byrka et al. (2010b) and Dannenberg et al. (2015) and the references therein.

Below, we investigate how the computational complexity of the basic problem varies according to which types of inputs are allowed and present some new results that expose the boundary between efficiently solvable and intractable versions of the problem.

1.1. Problem definitions

A phylogenetic tree is a rooted, unordered, distinctly leaf-labeled tree in which every internal node has at least two children (from here on, phylogenetic trees are simply referred to as “trees” and every leaf in a tree is identified with its corresponding leaf label). For any tree $T$, the set of all nodes in $T$ denoted by $V(T)$ and the set of all leaf labels occurring in $T$ is denoted by $\Lambda(T)$. The degree of a node $u \in V(T)$ is the number of children of $u$, and the degree of $T$ is the maximum degree of all nodes in $V(T)$. For any $u, v \in V(T)$, $\text{lca}^T(u, v)$ denotes the lowest common ancestor in $T$ of $u$ and $v$.

A rooted triplet is a tree with precisely three leaves. Let $t$ be any rooted triplet and suppose that $\Lambda(t) = \{x, y, z\}$. If $t$ is binary, then $t$ is called a resolved triplet and we write $t = xy|z$, where $\text{lca}^T(x, y)$ is a proper descendant of $\text{lca}^T(x, z) = \text{lca}^T(y, z)$. On the other hand, if $t$ is not binary, then $t$ is called a fan triplet and we write $t = xyz$. Note that there are four different rooted triplets leaf-labeled by $\{x, y, z\}$, namely $xy|z$, $xz|y$, $yz|x$, and $xyz$.

For any tree $T$ and $\{x, y, z\} \subseteq \Lambda(t)$, the resolved triplet $xy|z$ is consistent with $T$ if $\text{lca}^T(x, y)$ is a proper descendant of $\text{lca}^T(x, z) = \text{lca}^T(y, z)$. Similarly, the fan triplet $xyz$ is consistent with $T$ if $\text{lca}^T(x, y) = \text{lca}^T(x, z) = \text{lca}^T(y, z)$. Finally, for any tree $T$, let $\Lambda_T|\{x, y, z\}$ be the rooted triplet with leaf label set $\{x, y, z\}$ consistent with $T$, and let $\tau(T)$ be the set of all rooted triplets (resolved triplets as well as fan triplets) consistent with $T$, that is, define $\tau(T) = \{\Lambda_T|\{x, y, z\} : \{x, y, z\} \subseteq \Lambda(T)\}$.

The $R^+ \cap F^-$ Consistency problem:

Given two sets $R^+$ and $R^-$ of resolved triplets and two sets $F^+$ and $F^-$ of fan triplets over a leaf label set $L$, output a tree $T$ with $\Lambda(T) = L$ such that $R^+ \cup F^+ \subseteq \tau(T)$ and $(R^- \cup F^-) \cap \tau(T) = \emptyset$, if such a tree exists; otherwise, output null.

In other words, $R^+$ and $F^+$ specify rooted triplets that are required to be embedded in the output tree, while $R^-$ and $F^-$ are forbidden rooted triplets. See Figure 1 for two examples. Throughout the text, we use $n$ to denote the cardinality of the input leaf label set $L$.

The special cases of the $R^+ \cap F^-$ Consistency problem where one or more of the four input sets $R^+, R^-, F^+, F^-$ are empty will also be denoted by removing the corresponding “$+$” and “$-$” symbols from the problem name. For example, the $R^- \cap F^+$ Consistency problem requires that $R^+ = F^- = \emptyset$. To simplify the notation, if $R^+ = R^- = \emptyset$, then we omit the “$R^+$” and analogously for “$F^+$”; for example, $R^-$ means $R^+ = F^+ = F^- = \emptyset$. Ignoring the trivial case where all of $R^+, R^-, F^+, F^-$ are empty, this yields exactly 14 problem variants in addition to the original problem. Our goal is to establish the computational complexity of all these problem variants as well as some other potentially useful special cases.

**FIG. 1.** As an example, consider the following instance of the $R^+ \cap F^-$ Consistency problem: $L = \{a, b, c, d\}$, $R^+ = \emptyset$, $R^- = \{cd|a\}$, $F^+ = \{a|b|c\}$, and $F^- = \{b|c|d\}$. The shown tree $T$ satisfies $\tau(T) = \{a|b|c, bd|a, a|c|d, bd|c\}$, so $R^+ \cup F^+ \subseteq \tau(T)$ and $(R^- \cup F^-) \cap \tau(T) = \emptyset$ hold. Thus, $T$ is a valid solution. As another example, if $L, R^+, R^-$, and $F^-$ are the same as above but $F^+$ is changed to $F^+ = \{a|b|c, a|b|d\}$, then the answer is null.
1.2. Overview of old and new results

Aho et al. (1981) presented a polynomial-time algorithm named BUILD that solves the $\mathcal{R}^+$ Consistency problem, and a faster implementation of it was given by Henzinger et al. (1999). Ng and Wormald (1996) extended BUILD to solve $\mathcal{R}^+ \mathcal{F}^+$ Consistency in polynomial time, and He et al. (2006) later showed how to solve $\mathcal{R}^- \mathcal{F}^+$ Consistency in polynomial time using a similar approach. As for negative results, it is known that $\mathcal{R}^- \mathcal{F}^+$ Consistency is NP-hard under the additional constraint that the output tree is binary (Bryant, 1997, Theorem 2.20).

Three direct consequences of these previously known results are given in Section 2 (Lemmas 1, 2, and 3). In Section 3, we prove that the $\mathcal{F}^+ \mathcal{F}^+$ Consistency problem is NP-hard (Theorem 1). Lemmas 1, 2, and 3 together with Theorem 1 then provide a complete characterization of the polynomial-time solvability of all 15 variants of the $\mathcal{R}^+ \mathcal{F}^+ \mathcal{F}^+$ Consistency problem defined in Section 1.1 since each of the remaining problem variants is either a special case of a polynomial-time solvable problem variant or a generalization of an NP-hard one (see Table 1).

Motivated by these observations, we then try to identify some way of restricting the $\mathcal{R}^+ \mathcal{F}^+ \mathcal{F}^+$ Consistency problem that leads to more efficiently solvable problem variants. One natural restriction is to require the degree of the output tree to be at most $D$ for some integer $D \geq 2$; unfortunately, Section 4 demonstrates that this generally makes the problems harder. See Table 2 for a summary. In particular, Theorem 2 proves that even $\mathcal{F}^+ \mathcal{F}^+$ Consistency is NP-hard when restricted to degree-$D$ trees for every fixed $D \geq 4$. Furthermore, by Corollary 2, $D$-bounded degree $\mathcal{R}^- \mathcal{F}^+$ Consistency becomes NP-hard for every fixed $D \geq 2$. The only efficiently solvable problem variants that we know of are covered by Corollary 1, stating that $D$-bounded degree $\mathcal{R}^+ \mathcal{F}^+ \mathcal{F}^+$ Consistency remains polynomial-time solvable for every $D \geq 2$.

Therefore, we need to find another way to restrict the problem. For this purpose, Section 5 considers inputs that are dense in the sense that for each $L' \subseteq L$ with $|L'| = 3$, at least one rooted triplet $t$ with $A(t)=L'$ is specified in $\mathcal{R}^+, \mathcal{R}^-, \mathcal{F}^+$, or $\mathcal{F}^-$. As shown in Dannenberg et al., the maximization version of $\mathcal{R}^+ \mathcal{F}^+ \mathcal{F}^+$ Consistency (whose objective is to output a tree $T$ with $A(T)=L$ maximizing the value of $T(\mathcal{R}^+ \cup \mathcal{F}^+) + (\mathcal{R}^- \cup \mathcal{F}^-) \setminus T(\mathcal{R}^+ \cup \mathcal{F}^-)$, where $T(X)$ for any set $X$ of rooted triplets denotes the subset of $X$ consistent with $T$) admits a polynomial-time approximation scheme (PTAS) when restricted to dense inputs.

"NP-hard$^*$" (with an asterisk) means NP-hard for every fixed $D \geq 4$ and trivially polynomial-time solvable for $D=2$, while the complexity for $D=3$ is still open.
inputs, whereas no such PTAS is known for the nondense case. Actually, the nondense case of the maximization problem is APX-complete (Byrka et al., 2010a, Proposition 2). This gives us some hope that $R^+ - F^+$ Consistency may be easier for dense inputs. Although $R^- - F^-$ Consistency turns out to be NP-hard in the dense case by Lemma 3, $R^+ - F^+$ Consistency restricted to dense inputs indeed admits a polynomial-time algorithm (Theorem 4), and moreover, its time complexity is $O(n^3)$, which is optimal because the size of a dense input is $\Omega(n^3)$. The situation for dense inputs is summarized in Table 3.

### 2. PRELIMINARIES

This section lists some simple results that follow immediately from previous work.

**Lemma 1.** The $R^+ - F^+$ Consistency problem is solvable in polynomial time.

*Proof.** For any instance of $R^+ - F^+$ Consistency, by deleting each fan triplet of the form $x|y|z$ from $F^+$ and inserting the three resolved triplets $xy|z$, $xz|y$, $yz|x$ into $R^-$, one obtains an equivalent instance of $R^+ - F^-$ Consistency to which the MTT algorithm in He et al. (2006) can be applied. By Theorem 1 in He et al. (2006), the running time becomes $O(|R^+| \cdot n + (|R^-| + |F^+|) \cdot n \log n + n^2 \log n)$. ■

**Lemma 2.** The $R^+ - F^-$ Consistency problem is solvable in polynomial time.

*Proof.** For any instance of $R^+ - F^-$ Consistency, run the BUILD algorithm (Aho et al., 1981) with input $R^+$ and let $T$ be its output. If $T$ is not null then, as long as $T$ is nonbinary, select any internal node $u$ with degree larger than two and any two children $c_1$ and $c_2$ of $u$, remove the edges $\{u, c_1\}$ and $\{u, c_2\}$, create a new child $v$ of $u$, and insert the edges $\{v, c_1\}$ and $\{v, c_2\}$. Finally, output $T$. Since $T$ is binary, no fan triplets in $F^-$ are consistent with $T$.

The original implementation of BUILD by Henzinger et al. (1999) runs in $\min\{O(|R^+| \cdot \sqrt{n} + n), O(|R^+| + n^2 \log n)\}$ time, and by replacing the data structure for supporting dynamic graph connectivity queries by a more recent one by Wulff-Nilsen (2013), the $\sqrt{n}$-factor is reduced to $\frac{\log n}{\log \log n}$. Thus, the $R^+ - F^-$ Consistency problem is solvable in $\min\{O\left(|R^+| \cdot \frac{\log n}{\log \log n} + |F^-| + n\right), O(|R^+| + |F^-| + n^2 \log n)\}$ time. ■

**Lemma 3.** The $R^- - F^-$ Consistency problem is NP-hard, even if restricted to dense inputs.

*Proof.** According to Theorem 2.20 in Bryant (1997), the $R^- - F^-$ Consistency problem is NP-hard when the output tree is constrained to be binary (see also Section 4.2 below for some comments related to the correctness of Bryant’s proof). Given any instance of Bryant’s version of the problem consisting of a set $R$ of forbidden resolved triplets, construct an equivalent instance of the $R^- - F^-$ Consistency problem by letting $R^- = R$ and letting $F^-$ be the set of all $\left\lfloor \frac{|L|}{3} \right\rfloor$ fan triplets over the leaf label set $L = \bigcup_{t \in R} A(t)$ (note that $F^-$ is dense). The reduction is a polynomial-time reduction, so the latter problem is also NP-hard. ■
3. $\mathcal{F}^+\,$ CONSISTENCY IS NP-HARD

Here, we prove that the $\mathcal{F}^+\,$ CONSISTENCY problem is NP-hard by giving a polynomial-time reduction from the NP-hard problem SET SPLITTING (Garey and Johnson, 1979):

**SET SPLITTING:**
Given a set $S = \{s_1, s_2, \ldots, s_n\}$ and a collection $C = \{C_1, C_2, \ldots, C_m\}$ of subsets of $S$ where $|C_j| = 3$ for every $C_j \subseteq S$, does $(S, C)$ have a set splitting, that is, can $S$ be partitioned into two disjoint subsets $S'$ and $S''$ such that for every $C_j \in C$ it holds that $C_j$ is not a subset of $S'$ and $C_j$ is not a subset of $S''$?

We now describe the reduction. Given an instance $(S, C)$ of SET SPLITTING, where we assume without loss of generality that $\bigcup_{C_j \in C} C_j = S$, construct an instance of $\mathcal{F}^+\,$ CONSISTENCY as follows:

- Let $L = S \cup \{x, y, z', z''\} \cup \{z_j, \beta_j, \gamma_j : 1 \leq j \leq m\}$ be the leaf set.
- For $1 \leq j \leq m$, denote $C_j = \{c_j^1, c_j^2, c_j^3\}$, where $c_j^1, c_j^2, c_j^3 \in S$. Define $F^+ = \{x|z', y|z'', z|x|z''\}$ and $F^- = \{x|z', y|z'', z|x|z'\}$.
- Define $F^+ = \{x|z'|z'' : s_i \in S\}$.

The next lemma ensures the correctness of the reduction:

**Lemma 4.** $(S, C)$ has a set splitting if and only if there exists a tree $T$ with $A(T) = L$ such that $F^+ \subseteq t(T)$ and $F^- \cap t(T) = \emptyset$.

**Proof:** $\Rightarrow$ Suppose that $(S', S'')$ is a set splitting of $(S, C)$. Create a tree $T$ with $A(T) = L$ whose root has $4 + 2m$ children in the following way (refer to Fig. 2 for an illustration). First, let two leaves labeled by $x$ and $y$ as well as two internal nodes $u'$ and $u''$ be children of the root of $T$, and attach $1 + |S'|$ leaves labeled by $\{z'\} \cup S'$ and $1 + |S''|$ leaves labeled by $\{z''\} \cup S''$ as children of $u'$ and $u''$, respectively. Next, for each $C_j \in C$, exactly two of the three elements $c_j^1, c_j^2, c_j^3$ have the same parent in $T$ because $(S', S'')$ is a set splitting; let $u_j$ be this common parent. By definition, $u_j \in \{u', u''\}$. The three leaves $z_j, \beta_j, \gamma_j$ are inserted into $T$ according to which one of these cases holds:

- $c_j^1$ and $c_j^2$ have the same parent $u_j$: Attach a leaf labeled by $\gamma_j$ as a child of $u_j$ and two leaves labeled by $z_j, \beta_j$ as children of the root of $T$.
- $c_j^2$ and $c_j^3$ have the same parent $u_j$: Attach a leaf labeled by $\beta_j$ as a child of $u_j$ and two leaves labeled by $x_j, \gamma_j$ as children of the root of $T$.
- $c_j^1$ and $c_j^3$ have the same parent $u_j$: Attach a leaf labeled by $x_j$ as a child of $u_j$ and two leaves labeled by $\beta_j, \gamma_j$ as children of the root of $T$.

It is straightforward to verify that $F^+ \subseteq t(T)$ and $F^- \cap t(T) = \emptyset$.

$\Leftarrow$ Suppose that $T$ is a tree with $A(T) = L$ such that $F^+ \subseteq t(T)$ and $F^- \cap t(T) = \emptyset$. Let $r = lca^T(x, y)$. The node $r$ must be the root of $T$ because (1) $x|y|q \in t(T)$ for all $q \in \{z', z''\} \cup S$ and (2) for each $\delta_j \in \{z_j, \beta_j, \gamma_j\}, 1 \leq j \leq m$, there exists an $s_j \in S$ such that $x|s_j|\delta_j \in t(T)$. Let $T'$ (resp. $T''$) be the subtree of $T$ rooted at a child of $r$ which contains $z'$ (resp. $z''$); then, $T' \neq T''$ since $x|z'|z'' \in t(T)$ and $x$ cannot belong to $T'$ due to $x|y|z' \in t(T)$. Furthermore, each $s_j \in S$ belongs to either $T'$ or $T''$ since $s_j|z'|z'' \notin t(T)$.

**FIG. 2.** Let $(S, C)$ be an instance of SET SPLITTING with $S = \{s_1, s_2, s_3, s_4\}$ and $C = \{C_1, C_2, C_3\}$, where $C_1 = \{s_1, s_2, s_3\}$, $C_2 = \{s_1, s_3, s_4\}$, $C_3 = \{s_2, s_3, s_4\}$. The reduction defines $F^+ = \{x|z', x|z'', z|x|z'', x|s_1|\gamma_1, x|s_2|\beta_1, x|s_3|\beta_1, x|s_4|\gamma_1, x|s_1|\gamma_2, x|s_2|\beta_2, x|s_3|\beta_2, x|s_4|\gamma_2, x|s_1|\gamma_3, x|s_2|\beta_3, x|s_3|\beta_3, x|s_4|\gamma_3\}$ and $F^- = \{z'|z'', \ldots, z'|z''\}$. The instance $(S, C)$ has a set splitting $(S', S'')$ where $S' = \{s_1, s_3\}$ and $S'' = \{s_2, s_4\}$, and the shown tree $T$ constructed from $(S', S'')$ as in the proof of Lemma 4 satisfies $F^+ \subseteq t(T)$ and $F^- \cap t(T) = \emptyset$. 
Next, we show by contradiction that for every \( C_i \in C \), exactly one or two of the three elements \( e_i^1, e_i^2, e_i^3 \) belong to \( T' \) (and hence, exactly one or two of the three elements belong to \( T'' \)). Suppose that all three elements belong to \( T' \). The condition \( e_i^1|e_i^2|y, e_i^2|e_i^3|y, e_i^3|e_i^1|y \in t(T) \) implies that \( y_j, y_j, y_j \) also belong to \( T' \). However, then \( x(e_i^1|y_j), x(e_i^2|y_j), x(e_i^3|y_j) \) cannot be consistent with \( T \), which is impossible. In the same way, all three elements cannot belong to \( T'' \).

In summary, selecting \( S' = A(T') \cap S \) and \( S'' = A(T'') \cap S \) yields a set splitting of \( (S, C) \).

Since the reduction can be carried out in polynomial time, Lemma 4 gives:

**Theorem 1.** The \( F^+ \)-Consistency problem is NP-hard.

### 4. D-BOUNDED DEGREE \( R^+ \)-\( F^- \) CONSISTENCY

We now consider the computational complexity of \( D \)-bounded degree \( R^+ \)-\( F^- \) Consistency, that is, where the degree of the output tree is constrained to be at most \( D \) for some integer \( D \geq 2 \). First, by noting that the method in the proof of Lemma 2 always outputs a binary tree, we have the following:

**Corollary 1.** For every fixed \( D \geq 2 \), the \( D \)-bounded degree \( R^+ \)-\( F^- \) Consistency problem is solvable in polynomial time.

In contrast, many other variants become NP-hard, as shown in the rest of this section.

#### 4.1. \( D \)-bounded degree \( F^+ \) Consistency is NP-hard

This subsection proves that for every fixed integer \( D \geq 4 \), the \( D \)-bounded degree \( F^+ \) Consistency problem is NP-hard. The proof relies on a simple polynomial-time reduction from the \( K \)-Coloring problem, which is NP-hard for every fixed integer \( K \geq 3 \) (Garey and Johnson, 1979):

**K-Coloring:**

Given an undirected, connected graph \( G = (V, E) \), does \( G \) have a \( K \)-coloring, that is, can \( V \) be partitioned into \( K \) (possibly empty) disjoint subsets \( V_1, V_2, \ldots, V_K \) such that for every \( \{u, v\} \in E \) it holds that \( i \neq j \) where \( u \in V_i \) and \( v \in V_j \)?

The reduction is as follows. Given an instance of \((D-1)\)-Coloring, create an instance of \( D \)-bounded degree \( F^+ \) Consistency by setting \( L = V \cup \{x\} \) and \( F^+ = \{u|v : \{u, v\} \in E\} \). See Figure 3 for an example.

**Lemma 5.** \( G \) has a \((D-1)\)-coloring if and only if there exists a tree \( T \) with degree at most \( D \) and \( \Lambda(T) = L \) such that \( F^+ \subseteq t(T) \).

**Proof.** \( \Rightarrow \) Suppose that \( V_1, V_2, \ldots, V_{D-1} \) is a \((D-1)\)-coloring of \( G \). For each \( j \in \{1, 2, \ldots, D-1\} \), let \( T_j \) be an arbitrary binary tree with \( \Lambda(T_j) = V_j \). Construct a tree \( T \) of degree at most \( D \) by attaching a leaf labeled by \( x \) and the roots of \( T_j \) for all \( 1 \leq j \leq D-1 \) as children of a common root node. Clearly, \( \Lambda(T) = L \) and for every \( x|u|v \in F^+ \), it holds by definition that \( u \) and \( v \) belong to different \( T_j \)-subtrees, which gives \( x|u|v \in t(T) \).

\( \Leftarrow \) Suppose \( T \) is such a tree and let \( r \) be the root of \( T \). Let \( T' \) be the subtree rooted at a child of \( r \) that contains \( x \). First, observe that \( \Lambda(T') = \{x\} \) (otherwise, \( T' \) would also contain some \( u \in V \); however, since \( G \) is connected, there exists some \( v \in V \) with \( \{u, v\} \in E \) and thus \( x|u|v \notin t(T) \), which is a contradiction). Next, denote the children of \( r \) that are not equal to \( x \) by \( c_1, c_2, \ldots, c_{D-1} \) (if \( r \) has degree less than \( D \) then some \( c_j \)-nodes may be set to \( \emptyset \)) and for \( j \in \{1, 2, \ldots, D-1\} \), define \( V_j \) as the set of leaf labels that are connected to the children of \( r \). The \((D-1)\)-Coloring to \( D \)-bounded degree \( F^+ \) Consistency sets \( F^+ = \{x|a|b, x|a|c, x|a|e, x|b|d, x|b|e, x|c|e, x|c|f, x|d|e, x|e|f\} \). Suppose \( D=4 \) and consider the 3-coloring \( \{a, d, f\}, \{b, c\}, \{e\} \) of \( G \). The degree-4 tree \( T \) on the right, constructed according to the first part of the proof of Lemma 5, satisfies \( F^+ \subseteq t(T) \).
4.1. D-bounded degree $D$-bounded degree $\mathcal{R}^-$ consistency is NP-hard

Theorem 2.20 of Bryant (1997) states that the $D$-bounded degree $\mathcal{R}^-$ consistency problem is NP-hard for $D=2$. Its proof uses a polynomial-time reduction from the following NP-hard problem (Garey and Johnson, 1979):

**3SAT:**

- Given a set $U$ of Boolean variables and a collection $C = \{C_1, C_2, \ldots, C_m\}$ of disjunctive clauses over $U$, each containing exactly three literals, is there a truth assignment for $U$ that makes every clause in $C$ true?

The main idea in Bryant’s reduction is to represent every literal in the given instance of 3SAT by a leaf label and define the forbidden resolved triplets so that in any valid tree, assigning true to all literals contained in one particular subtree rooted at a child of the root (and assigning false to the rest) results in a valid truth assignment.

In this subsection, we adapt Bryant’s proof to obtain an analogous result for the case $D=3$ by introducing an additional leaf label $x$ and defining a slightly more involved set of forbidden resolved triplets. More precisely, given an instance of 3SAT, we construct an instance of 3-bounded degree $\mathcal{R}^-$ consistency with $L = U \cup \overline{U} \cup C \cup \{x,t,f\}$ and $R^- = R_1 \cup R_2 \cup R_3 \cup R_4$, where $\overline{U} = \{\overline{u} : u \in U\}$ and:

- $R_1 = \{tf|x, \overline{t}f|x, fx|t\}$.
- $R_2 = \{tf|u, \overline{t}f|u, \overline{u}f|u, \overline{u}f|t : u \in U\}$,
- $R_3 = \{f|C_j, C_j|t : C_j \in C\}$, and
- $R_4 = \{u_2v_2|C_j, w_2|C_j : C_j \in C\}$, where we write $C_j = (u_j \lor v_j \lor w_j)$ with $u_j, v_j, w_j \in U \cup \overline{U}$.

Note that $R_4$ is defined asymmetrically.

The correctness of the reduction follows from the next lemma.

**Lemma 6.** There is a truth assignment for $U$ making every clause in $C$ true if and only if there exists a tree $T$ with degree at most 3 and $A(T)=L$ such that $R^- \cap t(T) = \emptyset$.

**Proof.** $\Rightarrow$ Suppose $g : U \rightarrow \{\text{true}, \text{false}\}$ is a truth assignment making every clause in $C$ true. Extend $g$ to $\overline{U}$ by defining $g(\overline{u}) = \text{false}$ if $g(u) = \text{true}$, and $g(\overline{u}) = \text{true}$ if $g(u) = \text{false}$ for every $u \in U$. Partition $U \cup \overline{U}$ into $A_i$ and $A_\overline{f}$, where $A_i = \{z \in U \cup \overline{U} : g(z) = \text{true}\}$ and $A_\overline{f} = \{z \in U \cup \overline{U} : g(z) = \text{false}\}$. Also define $B_i = \{C_j \in C : g(u) = \text{true} \lor g(v) \lor g(w)\}$ and $B_{\overline{f}} = C \setminus B_i$.

Next, build a tree $T$ with $A(T) = L$ consisting of three subtrees attached to a common root node, as illustrated in Figure 4. The first subtree is a single leaf labeled $x$. The second subtree is a binary caterpillar (i.e., a binary tree in which every node has at most one child that is an internal node) whose leaves are labeled by $A_i \cup B_i \cup \{\text{true}, \text{false}\}$ in a way such that $t$ is at maximum distance from the root and every leaf in $A_i$ is closer to the root than any leaf in $B_i$. The third subtree is a binary caterpillar leaf-labeled by $A_\overline{f} \cup B_{\overline{f}} \cup \{\text{false}\}$ so that $f$ is at maximum distance from the root and every leaf in $A_\overline{f}$ is closer to the root than any leaf in $B_{\overline{f}}$.

It follows that $T$ is not consistent with any resolved triplet in $R^-$.  

$\Leftarrow$ Suppose that $T$ is such a tree. By $R_1 \cap t(T) = \emptyset$, we have $x|t|f \in t(T)$. Let $r = \text{lca}^T(x,t) = \text{lca}^T(x,f) = \text{lca}^T(t,f)$. Since $R_2 \cap t(T) = \emptyset$ and $R_3 \cap t(T) = \emptyset$, $T$ is not consistent with any resolved triplets of the form $tf|z$ with $z \in U \cup \overline{U} \cup C$, so the node $r$ is the root of $T$. Let $T_i$ (resp., $T_{\overline{f}}$) be the subtree rooted at a child of the root of $T$ that contains $t$ (resp., $f$). For every $u \in U$, one of $u$ and $\overline{u}$ belongs to $T_i$, and the other one to $T_{\overline{f}}$ because $R_2 \cap t(T) = \emptyset$ and the constraint that the root of $T$ has degree at most 3. Similarly, $R_3 \cap t(T) = \emptyset$ implies that for every $C_j \in C$, $C_j$ belongs to either $T_i$ or $T_{\overline{f}}$.

Now, consider any $C_j \in C$. If both of $u_j$ and $v_j$ belong to $T_f$ then since $u_jv_j|C_j \in R_3$ and $R_3 \cap t(T) = \emptyset$, the leaf $C_j$ must also belong to $T_f$. In this case, $w_j$ cannot belong to $T_f$ because $w_j|C_j \in R_4$. Thus, for each $C_j \in C$, at least one of its literals is in $T_i$, so setting the variables in $U \cap A(T_i)$ to true and the variables in $U \cap A(T_{\overline{f}})$ to false guarantees that each clause contains at least one true literal.
Theorem 3. For $D=3$, the $D$-bounded degree $R^-$ consistency problem is NP-hard.

Remark: There is an error in the last part of the proof of Theorem 2.20 in Bryant (1997). If, for some satisfied clause $C_j \subseteq C$, the first literal is set to true and the second and third literals are set to false then the leaf representing $C_j$, denoted by $w_j$ in Bryant (1997), will end up in the set $W_B$ and hence in the same subtree as the third literal $z_j$, so the tree $T$ in Bryant (1997) will be consistent with a forbidden resolved triplet $z_jw_jT$ (which is not allowed either). A correct proof of Bryant’s theorem can be obtained from the construction above by removing $x$ from $L$ as well as all resolved triplets involving $x$ from $R^-$, and requiring $T$ to be binary. After doing so, the proof here becomes identical to Bryant’s original proof but with the sets $W_A$ and $W_B$, corresponding to $B_i$ and $B_f$, respectively, redefined so that the error is fixed.

Corollary 2. For every fixed $D \geq 2$, the $D$-bounded degree $R^-$ consistency problem is NP-hard.

Proof. For $D \in \{2, 3\}$, see above. For $D \geq 4$, the NP-hardness follows from Theorem 2 and the polynomial-time reduction from the $D$-bounded degree $F^+$ consistency problem, which, for each fan triplet of the form $x|y|z$ in $F^+$, replaces it by three resolved triplets $xy|z|y$, $yz|x$ in $R^-$ so that any tree $T$ satisfies $F^+ \subseteq t(T)$ for the given $F^+$ if and only if $T$ satisfies $R^- \cap t(T) = \emptyset$ for the constructed $R^-$. ■

5. AN OPTIMAL ALGORITHM FOR DENSE $R^+ F^-$ CONSISTENCY

Recall from Section 1.2 that an input to $R^+ F^-$ consistency is called dense if, for every $L' \subseteq L$ with $|L'|=3$, at least one rooted triplet $t$ with $A(t) = L'$ is in $R^+$, $R^-$, $F^+$, or $F^-$. This section presents the main result of the article, namely an algorithm called DenseBuild that solves the special case $R^+ F^-$ consistency (i.e., where $R^- = \emptyset$) restricted to dense inputs, and shows that its running time is $O(n^5)$, which is optimal. Two tools used by DenseBuild are the fan graph and the clique graph, defined and studied in Section 5.1. Algorithm DenseBuild is presented in Section 5.2.

According to Section 1.2, $R^+ F^-$ consistency is NP-hard. Intuitively, the problem becomes easier for dense inputs because if $T$ is a tree consistent with the input, then the set $Z = \{x|y|z : x, y, z \in L \text{ and } x, y, z \text{ belong to three different subtrees attached to the root of } T\}$ forms a subset of $F^+$, in which case $F^+$ contains enough information to uniquely partition $L$ into the leaf label sets of the maximal proper subtrees of $T$ (see Lemma 7). Moreover, such a partition can be computed in polynomial time using Lemmas 9 and 10. In contrast, when the input to $R^+ F^-$ consistency is not dense or when one considers dense $R^+ F^+$ consistency, not all of $Z$ may appear in the input $F^+$. 

FIG. 4. Illustrating how a truth assignment for $U$ that makes all clauses in $C$ true yields a degree-3 tree $T$ with $R^- \cap t(T) = \emptyset$, based on the proof of Theorem 2.20 in Bryant (1997). In this example, three clauses $C_1 = (u_1 \lor u_2 \lor u_3), C_2 = (u_1 \lor \overline{u_2} \lor u_4), C_3 = (\overline{u_1} \lor \overline{u_2} \lor u_4)$ with $\{C_1, C_2, C_3\} \subseteq C$ are satisfied by a truth assignment $g$ that assigns $g(u_1) = \text{false}$, $g(u_2) = \text{true}$, $g(u_3) = \text{false}$, $g(u_4) = \text{true}$, so $C_1, C_3 \in B_t$ and $C_2 \in B_f$ in the construction.
5.1. The fan graph and the clique graph

Let \( L' \subseteq L \). Define \( R^+|L' = \{ t \in R^+ : A(t) \subseteq L' \} \), \( F^+|L' = \{ t \in F^+ : A(t) \subseteq L' \} \), and \( F^-|L' = \{ t \in F^- : A(t) \subseteq L' \} \). The fan graph \( G_L \) is the undirected graph \( (L', E') \), where for any \( x, y \in L' \), it holds that \( \{ x, y \} \in E' \) if and only if \( x|y|z \in F^+|L' \) for some \( z \in L' \) (see Fig. 5).

If \( T \) is a tree that is consistent with the input, then the degree of the root of \( T \) can be determined from \( G_L \) according to the next lemma.

**Lemma 7.** Suppose that \( |L| \geq 3 \) and there exists a tree \( T \) that is consistent with the input. Let \( p \) be the degree of the root of \( T \), let \( C_1, C_2, \ldots, C_m \) be the connected components of \( G_L \), and let \( A(C_i) \) for each \( i \in \{ 1, 2, \ldots, m \} \) be the set of vertices in \( C_i \). The following holds:

1. If \( m \geq 2 \) then \( p = 2 \). Furthermore, if \( S' \) is any binary tree with \( m \) leaves and for each \( i \in \{ 1, 2, \ldots, m \} \), \( S_i \) is a tree with \( A(S_i) = A(C_i) \) such that \( (F^+|A(C_i)) \subseteq t(S_i) \) and \( (F^-|A(C_i)) \cap t(S_i) = \emptyset \), then the tree \( S \) obtained by replacing the \( m \) leaves in \( S' \) by the trees in \( \{ S_i : 1 \leq i \leq m \} \) satisfies \( F^+ \subseteq t(S) \) and \( F^- \cap t(S) = \emptyset \).

2. If \( m = 1 \) then \( p \geq 3 \). Furthermore, the value of \( p \) and the partition of \( L \) into subsets \( L_1, L_2, \ldots, L_p \) are unique, where each \( L_i \) is the leaf label set of a subtree rooted at a child of the root of \( T \).

**Proof.**

1. First we show that \( p = 2 \) by contradiction. Suppose \( p \geq 3 \) and let \( x, y, z \) be any three leaves from three different subtrees rooted at the children of the root of \( T \). Since the input is dense, at least one rooted triplet \( r \) with \( A(t) = \{ x, y, z \} \) is specified in \( R^+ \), \( F^+ \), or \( F^- \); by the choice of \( x, y, z \), it has to be \( x|y|z \). However, then the edges \( \{ x, y \}, \{ x, z \}, \) and \( \{ y, z \} \) are in \( G_L \) so \( x, y, \) and \( z \) belong to the same connected component \( C_i \). By repeating the argument, every leaf in \( L \) belongs to \( C_i \), which contradicts \( m \geq 2 \).

Next, consider any two connected components \( C_i \) and \( C_j \) in \( G_L \). By the definition of \( G_L \), there is no fan triplet in \( F^+ \) with leaves belonging to both \( C_i \) and \( C_j \). Hence, \( F^+ \) equals \( \bigcup_{i=1}^{m} (F^+|A(C_i)) \). By the definition of \( S, \bigcup_{i=1}^{m} (F^+|A(C_i)) \subseteq t(S) \). Finally, since \( S \) is binary, \( F^- \cap t(S) = F^- \cap \bigcup_{i=1}^{m} t(S_i) = 0 \).

2. To prove that \( p \geq 3 \), suppose on the contrary that \( p = 2 \). Let \( A \) and \( B \) be the two sets of leaves in the subtrees rooted at the two children of the root of \( T \). Since \( G_L \) is connected, there exist some \( a \in A \) and \( b \in B \) such that \( \{ a, b \} \) is an edge of \( G_L \). By the definition of \( G_L \), there exists some \( c \in L \) where \( a|b|c \in F^+ \). However, this is impossible since \( p = 2 \). This gives \( p \geq 3 \).

Next, we prove the uniqueness of the partition of \( L \) by contradiction. Suppose that \( T_j \) and \( T_k \) are two trees with \( F^+ \subseteq t(T_j) \), \( F^+ \subseteq t(T_k) \), and \( F^- \cap t(T_j) = F^- \cap t(T_k) = \emptyset \) and that the partitions of \( L \) induced by the children of the root of \( T_i \) are different for \( i = 1 \) and \( i = 2 \). For \( i \in \{ 1, 2 \} \), denote the root of \( T_i \) by \( r_i \).

We claim that there exist \( x, y, z \in L \) such that for some \( i \in \{ 1, 2 \} \): (1) \( x, y \) appear in the same subtree rooted at a child of \( r_i \) and \( z \) in another such subtree; and (2) \( x, y, z \) appear in three different subtrees rooted at the children of \( r_{3-i} \). To prove the claim, for some \( i \in \{ 1, 2 \} \), take any two leaves \( x \) and \( y \) in the same subtree \( D_i \) rooted at a child of \( r_i \) but in different subtrees \( D_{1-i}, D'_{1-i} \) rooted at a child of \( r_{3-i} \). Without loss of generality, assume \( i = 1 \). If there exists a leaf \( z \) in another subtree \( D'_1 \) rooted at a child of \( r_2 \) and \( z \) belongs to a subtree \( D''_2 \) rooted at a child of \( r_2 \) different from \( D_2 \) and \( D''_2 \), then we are done. Otherwise, all leaves not in \( D_2 \) or \( D'_2 \) also appear in \( D_1 \) and we let \( a \) be any such leaf; moreover, all leaves not in \( D_1 \) appear in either \( D_2 \) or \( D'_2 \) and we let \( b \) be any such leaf. Now, we define \( w \) as follows: (i) \( w = x \) if \( b \) and \( y \) are in the same subtree rooted at a child of \( r_2 \), and (ii) \( w = y \) if \( b \) and \( x \) are in the same subtree. The three leaves \( a, b, \) and \( w \) then satisfy the claim.

**FIG. 5.** An example. The fan graph \( G_L \) for \( L = \{ a, b, c, d, e, f, g, i, j \} \) and \( F^+ = \{ a|b|c, a|b|d, e|f|g, h|i|j \} \) is shown above. Since \( G_L \) has more than one connected component, Lemma 7 tells us that the root of any tree that is consistent with \( F^+ \) has exactly two children.
Since the claim is true, \( |y|z \notin t(T_i) \) while \( x|y|z \in t(T_{T_{j-1}}) \). This means that if \( x|y|z \in F^+ \) then \( F^+ \subseteq t(T_i) \) is false, if \( x|y|z \in F^- \) then \( F^- \cap t(T_{T_{j-1}}) \) is false, and if one of \( xy|z \), \( xz|y \), and \( yz|x \) is in \( R^+ \) then \( R^+ \subseteq t(T_{T_{j-1}}) \) is false, giving a contradiction in every case.

The lemmas below are used by DenseBuild in Section 5.2 to construct the partition in Lemma 7.2. In the rest of this subsection, assume that \( G_L \) contains a single connected component and that there exists a tree \( T \) that is consistent with the input. For every \( \ell \in L \), let \( T_\ell \) denote the subtree attached to the root of \( T \) that contains \( \ell \). Also, for every \( a, b \in L \), define \( f(a, b) = |\{ z : a|b|z \in F^+ \}| \).

**Lemma 8.** If \( a, b \in L \) are any two leaves that maximize the value of \( f(a, b) \), that is, \( f(a, b) = \max_{x, y \in L} f(x, y) \), then \( a \) and \( b \) belong to two smallest subtrees rooted at children of the root of \( T \) with \( T_a \neq T_b \). Furthermore, \( f(a, b) = |A(T)| - |A(T_a)| - |A(T_b)| \).

**Proof.** Consider any \( x, y \in L \) and define \( s = \text{lca}(x, y) \). \( G_L \) consists of one connected component, so \( T \) has at least three subtrees attached to the root according to Lemma 7.2. If \( T_x = T_y \), that is, if \( s \) is not the root of \( T \), then let \( x', y' \in L \) be two leaves from two other subtrees attached to the root. Since the input is dense, for every \( x|y|z \in F^+ \), the fan triplet \( x'|y'|z \) also belongs to \( F^+ \). Together with \( x'|y'|x \in F^* \) and \( x'|y'|y \in F^* \), we get \( f(x', y') > f(x, y) \). Thus, to maximize \( f(x, y) \), \( s \) must be the root of \( T \).

Next, for every \( z \in A(T) \setminus (A(T_a) \cup A(T_b)) \), we have \( x|y|z \in F^+ \) because the input is dense, which gives \( f(x, y) = |A(T)| - |A(T_a)| - |A(T_b)| \). From this formula, one can see that \( T_x \) and \( T_y \) have to be two smallest subtrees attached to the root of \( T \) to make the value of \( f(x, y) \) as large as possible.

**Lemma 9.** Let \( a, b \in L \) be two leaves that maximize the value of \( f(a, b) \). Define \( L' = \{a, b\} \cup \{x \in L : a|b| x \notin F^+ \} \) and take any \( z \in L' \setminus L \). Then the leaf label sets of two smallest subtrees attached to the root of \( T \) are \( A = \{a\} \cup \{x \in L' : a|x|z \notin F^+ \} \) and \( B = L' \setminus A = \{b\} \cup \{x \in L' : b|x|z \notin F^+ \} \).

**Proof.** By Lemma 8, \( a \) and \( b \) appear in two smallest subtrees \( T_a \) and \( T_b \) attached to the root of \( T \). For every leaf label \( x \) in \( T_a \) or \( T_b \), \( a|b| x \notin F^+ \). Thus, \( L' = A(T_a) \cup A(T_b) \). Since \( z \notin L' \), \( z \) is not in the subtrees containing \( a \) and \( b \). On the other hand, for every leaf \( x \) in \( T_a \) with \( x \neq a \), we have \( x \in L' \) and therefore \( a|x|z \notin F^+ \). Hence, \( A(T_a) = \{a\} \cup \{x \in L' : a|x|z \notin F^+ \} \). In the same way, \( A(T_b) = \{b\} \cup \{x \in L' : b|x|z \notin F^+ \} \).

Finally, suppose that \( a, b, \) and \( L' \) are defined as in Lemma 9. The clique graph \( Q_L \) is the undirected graph \((L'', E'')\), where \( L'' = L' \setminus L \) and \( \{x, y\} \in E'' \) if and only if \( a|x|y \notin F^+ \) (or equivalently, \( b|x|y \notin F^+ \)) (see Fig. 6). The clique graph has the following useful property.

**Lemma 10.** Let \( C \) be any connected component in \( Q_L \). Then \( C \) forms a complete graph, and moreover, the set of vertices in \( C \) equals the set of leaves in some subtree attached to the root of \( T \).

**Proof.** By the definition of \( L' \), if \( x \in L' \setminus L \) then \( T_x \neq T_y \).

Suppose that \( C \) is a connected component in \( Q_L \) with two edges of the form \( \{x, y\}, \{z, y\} \). Then \( a|x|y \notin F^+ \). Since \( x \) and \( y \) do not belong to \( T_a \), we have \( T_x = T_y \). Similarly, \( a|x|z \notin F^+ \) yields \( T_x = T_z \). By transitivity, \( T_x = T_y = T_z \), so \( a|x|y \notin F^+ \) and \( \{x, y\} \in E'' \), which implies that \( C \) is a complete graph. Also, for any vertex \( x \) in \( C \), the fact that \( a|x|y \notin F^+ \) for any other vertex \( y \) in \( C \) means that either \( a|x|y \in F^+ \) or \( x|y|a \in R^+ \) because the input is dense, which then yields \( T_x = T_y \). In other words, all vertices in \( C \) belong to a single subtree attached to the root of \( T \).

Conversely, consider any subtree \( T' \) attached to the root of \( T \) with \( T' \neq T_a \). For every pair of vertices \( x, y \) in \( T' \), \( \{x, y\} \in E'' \) because \( a|x|y \notin F^+ \), so the set of leaves in \( T' \) induces one connected component in \( Q_L \).
Thus, Lemma 9 lets us identify the leaf label sets of two different subtrees attached to the root of $T$. After that, according to Lemma 10, the leaf label sets of the remaining subtrees can be obtained by taking the connected components in the clique graph $Q_L$.

### 5.2. Algorithm DenseBuild

We now develop an efficient algorithm for $\mathcal{R}^+\mathcal{F}^+\mathcal{-}$ CONSISTENCY restricted to dense inputs. The algorithm is named DenseBuild and its pseudocode is summarized in Figure 7 (refer to Section 5.1 for the notation defined there). The basic strategy is to use the information contained in $R^+$, $F^+$, and $F^-$ to partition the leaf label set $L$ into subsets corresponding to the leaf label sets of the subtrees rooted at the children of the root of the solution, and then construct each such subtree recursively. On a high level, this is similar to the BUILD algorithm of Aho et al. (1981), which also uses top-down recursion, but DenseBuild has to do the leaf partitioning in a different way to take the fan triplets into account. Also, DenseBuild needs to distinguish between when the root has degree 2 and degree strictly larger than 2 (cf., Lemma 7).

As a preprocessing step, DenseBuild constructs the fan graph $G_L$ and assigns a weight $w(x,y)$ to each edge $\{x,y\}$ in $G_L$ equal to $|\{z \in F^+ : z \in L\}|$. In the preprocessing step, the algorithm also computes and stores the value $f(a,b)$ for every $a, b \in L$. The next lemma shows that when the algorithm calls itself recursively, it does not have to recompute any $f(a,b)$-values. For any $L' \subseteq L$ and $a, b \in L'$, define $f_L(a,b)=|\{z : a|b|z \in F^+[L']\}|$.

**Lemma 11.** Suppose that $T$ is a tree with $A(T)=L$ and that $T$ is consistent with the input. Let $L' \subseteq L$ be the set of leaves in a subtree rooted at any child of the root of $T$. Then $f_L(a,b)=f_L(a,b)=f(a,b)$ for every $a, b \in L'$.

**Proof.** Fix $a, b \in L'$. For any fan triplet of the form $a|b|z \in F^+$, $z$ also has to belong to $L'$, and therefore $a|b|z \in F^+[L']$. Conversely, $a|b|z \in F^+[L']$ implies $a|b|z \in F^+$. Hence, $\{z : a|b|z \in F^+[L']\}=\{z : a|b|z \in F^+\}$.

After the preprocessing step is complete, DenseBuild proceeds as follows. It computes the connected components $C_1, C_2, \ldots, C_m$ of $G_L$ in step 1. According to Lemma 7, there are two main cases: if $m \geq 2$ then the root of any tree consistent with the input must have degree 2, but if $m=1$ then the root must have degree at least 3.

In the former case (steps 2.1–2.3), the algorithm recursively constructs a tree $T_i$ for the leaves in $C_i$ for each $i \in \{1, 2, \ldots, m\}$, thus handling the input rooted triplets over leaves within each connected component. To handle the rest, that is, those whose leaves belong to more than one connected component in $G_L$, the algorithm constructs an instance of nondense $\mathcal{R}^+\mathcal{F}^+\mathcal{-}$ CONSISTENCY whose leaf label set represents the set of connected components in $G_L$ and whose set of resolved triplets is $\{C_iC_jC_k : \exists x, y, z \in R^+ \text{ with } x \in C_i, y \in C_j, z \in C_k\}$. It then applies the BUILD algorithm from Aho et al. (1981) to obtain a tree $T'$ (if one exists) consistent with all resolved triplets in $R^+$ involving leaves from more than one connected component (if no such $T'$ exists or if some $T_i$-tree is null, then DenseBuild will also return null and give up at this point). Then, DenseBuild arbitrarily refines $T'$ into a binary tree as in the proof of Lemma 2 above. Finally, the output tree $T$ is obtained by replacing each $C_i$-leaf in $T'$ by the corresponding $T_i$-tree. By Lemma 7.1, $T$ is consistent with all fan triplets in $F^+$ and no fan triplets in $F^-$. 

In the latter case (steps 3.1–3.4.4), Lemma 7.2 ensures that the partition of $L$ into leaf label sets of the subtrees rooted at the children of the root is uniquely defined. This partition is recovered in steps 3.1–3.3 in accordance with Lemmas 9 and 10. Next, step 3.4 verifies that the resulting partition $L_1, L_2, \ldots, L_p$ is valid by checking if $x|y|z \in F^+$ and $x|y|z \notin R^+$ hold for every $x \in L_i, y \in L_j, z \in L_k$ where $i, j, k$ are different. If the partition is valid then, for each $i \in \{1, 2, \ldots, p\}$, the algorithm first constructs $G_{L_i}$ (to avoid building $G_L$ from scratch, the weight $w(x,y)$ of each edge $\{x,y\}$ in $G_L$ is updated by subtracting 1 for every fan triplet $x|y|z \in F^+$ that contributed to $w(x,y)$ in $G_L$ but no longer exists on subsequent recursion levels; any edge whose weight reaches 0 is removed). Then, it recursively builds a tree $T_i$ with $A(T_i)=L_i$. The output tree $T$ is formed by attaching the roots of all the $T_i$-trees to a common root node.

**Theorem 4.** Algorithm DenseBuild solves the dense variant of the $\mathcal{R}^+\mathcal{F}^+\mathcal{-}$ CONSISTENCY problem in $O(n^3)$ time.
Algorithm DenseBuild

Input: Three sets $R^+, F^+, F^-$ of rooted triplets over a leaf label set $L$ forming a dense instance of $\mathcal{R}^{+}F^{+}$. The algorithm assumes the following preprocessing: $\mathcal{G}_L$ is constructed and edge-weighted, and $f(a,b)$ for all $a,b \in L$ have been precomputed.

When making recursive calls, the algorithm passes $L' \subseteq L$ and $\mathcal{G}_{L'}$ as parameters.

Output: A tree $T$ with $\lambda(T) = L$ such that $R^+ \cup F^+ \subseteq t(T)$ and $F^- \cap t(T) = \emptyset$, if such a tree exists; otherwise, $null$.

1 Let $C_1, C_2, \ldots, C_m$ be the connected components of $\mathcal{G}_L$;

2 if $(m > 1)$ then

2.1 For $i \in \{1, 2, \ldots, m\}$, extract $\mathcal{G}_{L_i}$ from $\mathcal{G}_L$ and compute $T_i = DenseBuild(L_i, \mathcal{G}_{L_i})$, where $L_i$ is the set of leaf labels in $C_i$;

2.2 Let $R' = \{C_iC_j|C_k : \exists xy|z \in R^+ \text{ with } x \in C_i, y \in C_j, z \in C_k\}$ and let $T'$ be the output of the BUILD algorithm on input $R'$;

2.3 if $T' = null$ or $T_i = null$ for any $i \in \{1, 2, \ldots, m\}$ then return $null$;

else let $T$ be the tree obtained by arbitrarily refining $T'$ to a binary tree and replacing each leaf $C_i$ in $T'$ by the tree $T_i$, and return $T$;

else

3 /* $(m = 1)$ */

3.1 Find $a,b \in L$ that maximize $f(a,b)$;

3.2 Let $L' = \{a,b\} \cup \{x : a|x|b \in F^+\}$, $z \in L \setminus L'$, $L_1 = \{a\} \cup \{x \in L' : a|x|z \notin F^+\}$, and $L_2 = L' \setminus L_1$;

3.3 Build the clique graph $\mathcal{Q}_L$ and let $L_3, \ldots, L_p$ be the leaf labels in the different connected components in $\mathcal{Q}_L$;

3.4 if $\{(x|y|z : x \in L_i, y \in L_j, z \in L_k, \text{ where } i,j,k \text{ are different} \} \subseteq F^+$ and $(xy|z \in R^+: x \in L_i, y \in L_j, z \in L_k, \text{ where } i,j,k \text{ are different}) = \emptyset$ then

3.4.1 Decrement $w(x,y), w(x,z)$, and $w(y,z)$ by one for every $x|y|z \in F^+$ such that $x \in L_i, y \in L_j, z \in L_k$, and $i,j,k$ are different;

3.4.2 For $i \in \{1, 2, \ldots, p\}$, extract $\mathcal{G}_{L_i}$ from $\mathcal{G}_L$ and compute $T_i = DenseBuild(L_i, \mathcal{G}_{L_i})$;

3.4.3 if $T_i = null$ for any $i \in \{1, 2, \ldots, p\}$ then return $null$;

else create a tree $T$ by attaching the root of $T_i$ for every $i \in \{1, 2, \ldots, p\}$ to a common root node and return $T$;

else

3.4.4 return $null$;

endif

End DenseBuild

FIG. 7. Algorithm DenseBuild.
Proof. The preprocessing step constructs $G_L$, assigns weights to the edges in $G_L$, and computes all values of $f(a, b)$ where $a, b \in L$, which takes $T_\ell(n) = O(n^3)$ time in total. We now bound the time needed to execute DenseBuild($L, G_L$) assuming that the preprocessing has been taken care of. Let $T_B(n)$ be the total time used by the calls to BUILD in step 2.2 on all recursion levels, and let $T_C(n)$ be the total time for all other computations.

To analyze $T_B(n)$, let $n_1, n_2, \ldots, n_k$ be the cardinalities of the leaf label sets of the constructed sets $R'$ of resolved triplets in the successive calls to BUILD in step 2.2. By applying Henzinger et al.’s fast implementation of BUILD [Algorithm B’ in Henzinger et al. (1999)], we get $T_B(n) = \sum_{i=1}^{k} O(n_i^2 + n_i^2 \log n_i) = O\left(\sum_{i=1}^{k} n_i^3\right)$. Also, $n_1 + n_2 + \cdots + n_k = O(n)$ because every leaf in each such constructed instance of $R'^{\text{Consistency}}$ corresponds to either an internal node or a leaf in the tree output by DenseBuild, which has $O(n)$ nodes. Thus, $T_B(n) = O(n^3)$.

Next, we derive an upper bound on $T_C(n)$. For any partition of $L$ into $L_1, L_2, \ldots, L_m$, let $c(L_1, L_2, \ldots, L_m)$ denote the number of possible fan triplets of the form $x|y|z$ such that $x \in L_i, y \in L_j, z \in L_k$ and $i, j, k$ are different. Observe that $c(L_1, L_2, \ldots, L_m) = O\left(\left(\frac{|L|}{3}\right)^3 - \sum_{i=1}^{m} \left(\frac{|L_i|}{3}\right)^3\right)$.

Then $T_C(n)$ consists of the time needed to find the $m$ connected components in $G_L$, which is $O(|L|^2)$, plus the time to:

- If $m \geq 2$:
  (a) Build $G_{L_i}$ for all $i \in \{1, 2, \ldots, m\}$. This takes $O(c(L_1, L_2, \ldots, L_m))$ time.
  (b) Construct $R'$. This also takes $O(c(L_1, L_2, \ldots, L_m))$ time.
  (c) Handle the recursive calls. This takes $\sum_{i=1}^{m} T_C(|L_i|)$ time.
- If $m = 1$:
  (a) Find the partition of $L$ into $L_1, L_2, \ldots, L_p$ in steps 3.1–3.3. This takes $O(|L|^2)$ time.
  (b) Verify that the partition is valid in step 3.4. This takes $O(c(L_1, L_2, \ldots, L_p))$ time.
  (c) Handle the recursive calls. This takes $T_C(|L|)$ time.

Define $q = \max\{m, p\}$. In total, $T_C(n) = O(|L|^2) + O(c(L_1, L_2, \ldots, L_q)) + \sum_{i=1}^{q} T_C(|L_i|)$, which gives $T_C(n) = O(n^3)$ by induction.

Finally, $T_\ell(n) + T_B(n) + T_C(n) = O(n^3)$.

6. CONCLUDING REMARKS

The decision problem version of the $R'^{\text{Consistency}} \rightarrow F'^{\text{Consistency}}$ problem belongs to NP since given any instance along with a candidate tree $T$, one can check in polynomial time whether $A(T) = L$, $R^+ \cup F^+ \subseteq \iota(T)$, and $(R'^+ \cup F'^+) \cap \iota(T) = \emptyset$ hold. For every NP-hard variant of $R'^{\text{Consistency}} \rightarrow F'^{\text{Consistency}}$ studied in this article, its corresponding decision problem is also NP-hard by the reductions used in Lemmas 3–6, Corollary 2, and Theorem 2.20 in Bryant (1997), and thus NP-complete.

The newly derived results (see Tables 1–3 for a summary) highlight the following open problems:

- What is the computational complexity of the $D$-bounded degree $F'$ CONSISTENCY problem when $D = 3$? That is, is the following problem solvable in polynomial time: Given a set $F'$ of fan triplets, does there exist a degree-3 tree consistent with all of $F'$?
- For the special case of $D = 3$, do the following problems have the same computational complexity or not: $D$-bounded degree $F'$ CONSISTENCY, $D$-bounded degree $F'^-$ CONSISTENCY, $D$-bounded degree $R^+ F'^-$ CONSISTENCY, and $D$-bounded degree $R'^+ F'^-$ CONSISTENCY?
- How does the complexity of $R'^- F'^-$ CONSISTENCY and its problem variants change when other parameters such as the height of the output tree are restricted or if one requires the output tree to be ordered in such a way that its left-to-right sequence of leaves must equal a prespecified sequence? Note that the analog of $R^+ \text{CONSISTENCY}$ in the unrooted setting where the input is a set of “quartets” (unrooted, distinctly leaf-labeled trees with four leaves where every internal node has three neighbors) is already NP-hard (Steel, 1992).
- Can fixed-parameter tractable algorithms be developed for any of the NP-hard variants of $R'^- F'^-$ CONSISTENCY?
One may define several optimization problems based on the $R^+ \land F^+ \land Consistency$ problem. One example is the maximization problem referred to at the end of Section 1.2. Another example is a minimization version of the $D$-bounded degree $F^+$ Consistency problem in which the input is a set $F^+$ of fan triplets and the objective is to construct a tree with as small degree as possible that is consistent with all fan triplets in $F^+$. However, this is a difficult problem because Lemma 5 and the polynomial-time inapproximability result for the minimization version of $K$-Coloring in Theorem 1.2 of Zuckerman (2007) imply that the problem cannot be approximated within a ratio of $n^{1-\epsilon}$ for any constant $\epsilon > 0$ in polynomial time, unless $P=NP$.

Another related optimization problem requires that the output tree has the smallest possible number of internal nodes among all valid solutions; such a tree is called a minimally resolved supertree. Section 2.5.2 in Bryant (1997) proved that BUILD does not always return a minimally resolved supertree, and in fact this minimization problem cannot be approximated within a ratio of $n^{1-\epsilon}$ for any constant $\epsilon > 0$ in polynomial time unless $P=NP$ (Jansson et al., 2012). It is known that a minimally resolved supertree can be computed in $O(2.733^n)$ time when $R^-=F^+=F^-\emptyset$ by dynamic programming (Jansson and Sung, 2016) and it is an open problem to extend this algorithm to deal with inputs containing fan triplets and forbidden triplets.
