82720

GRAPHICS DISPLAY CONTROLLER

- Displays Low-to-High Resolution Images
- Draws Characters, Points, Lines, Arcs, and Rectangles
- Supports Monochrome, Gray Scale, or Color Displays
- Zooms, Pans and Windows Through a 4 Mpixel Display Memory
- Extremely Flexible Programmable Screen Display, Blanking, and Sync Formats
- Compatible with Intel's Microprocessor Families
- High-Level Commands Off Load Host Processor from Bit Map Loading and Screen Refresh Tasks
- Supports Graphics, Character, and Mixed Display Modes

FUNCTIONAL DESCRIPTION

Introduction

The 82720 Graphics Display Controller (GDC) is an intelligent microprocessor peripheral designed to drive high-performance raster-scan computer graphics and character CRT displays. Positioned between the video display memory and Intel microprocessor bus, the GDC performs the tasks needed to generate the raster display and manage the display memory. Processor software overhead is minimized by the GDC's sophisticated instruction set, graphics figure drawing, and DMA transfer capabilities. The display memory directly supported by the GDC can be configured in any number of formats and sizes up to 256K 16-bit words. The display can be zoomed and partitioned screen areas can be independently scrolled and panned. With its light pen input and multiple controller capability, the GDC is ideal for most computer graphics applications. Systems implemented with the GDC can be designed to be compatible with standards such as VDI, NAPLPS, GKS, Core, or custom implementations.

FUNCTIONAL DESCRIPTION (Continued)

Microprocessor Bus Interface

Control of the GDC by the system microprocessor is achieved through an 8-bit bidirectional interface. The status register is readable at any time. Access to the FIFO buffer is coordinated through flags in the status register.

Command Processor

The contents of the FIFO are interpreted by the command processor. The command bytes are decoded, and the succeeding parameters are distributed to their proper destinations within the GDC. The bus interface has priority over the command processor when both access the FIFO simultaneously.

DMA Control

The DMA Control circuitry in the GDC coordinates data transfers when using an external DMA controller. The DMA Request and Acknowledge handshake lines interface with an 8257 or 8237 DMA controller or 8089 I/O processor, so that display data can be moved between the microprocessor memory and the display memory.

Parameter RAM

The 16-byte RAM stores parameters that are used repetitively during the display and drawing processes. In character mode, the RAM holds the partitioned display area parameters. In graphics mode, the RAM also holds the drawing pattern and graphics character.

Video Sync Generator

Based on the clock input, the sync logic generates the raster timing signals for almost any interlaced, non-interlaced, or "repeat field" interlaced video format. The generator is programmed during the idle period following a reset. In video sync slave mode, it coordinates timing between the GDC and another video source.

Memory Timing Generator

The memory timing circuitry provides two memory cycle types: a two-clock period refresh cycle and the read-modify-write (RMW) cycle which takes four clock periods. The memory control signals needed to drive the display memory devices are easily generated from the GDC's RAS(ALE) and DBIN outputs.

Zoom and Pan Controller

Based on the programmable zoom display factor and the display area parameters in the parameter RAM, the zoom and pan controller determines when to advance to the next memory address for display refresh and when to go on to the next display area. A horizontal zoom is produced by slowing down the display refresh rate while maintaining the video sync rates. Vertical zoom is accomplished by repeatedly accessing each line a number of times equal to the horizontal repeat. Once the line count for a display area is exhausted, the controller accesses the starting address and line count of the next display area from the parameter RAM. The system microprocessor, by modifying a display area starting address, allows panning in any direction, independent of the other display areas.

Drawing Processor

The drawing processor contains the logic necessary to calculate the addresses and positions of the pixels of the various graphics figures. Given a starting point and the appropriate drawing parameters, the drawing processor needs no further assistance to complete the figure drawing.

Display Memory Controller

The display memory controller's tasks are numerous. Its primary purpose is to multiplex the address and data information in and out of the display memory. It also contains the 16-bit logic units used to modify the display memory contents during RMW cycles, the character mode line counter, and the refresh counter for dynamic RAMs. The memory controller apportions the video field time between the various types of cycles.

Light Pen Debouncer

Only if two rising edges on the light pen input occur at the same point during successive video fields are the pulses accepted as a valid light pen detection. A status bit indicates to the system microprocessor that the light pen register contains a valid address.

System Operation

The GDC is designed to work with Intel microprocessors to implement high-performance computer graphics systems. System efficiency is maximized through partitioning and a pipelined architecture. At the lowest level, the GDC generates the basic video...
raster timing, including sync and blanking signals. Partitioned areas on the screen and zooming are also accomplished at this level. At the next level, video display memory is modified during the figure drawing operations and data moves. Third, display memory address are calculated pixel by pixel as drawing progresses. Outside the GDC at the next level, preliminary calculations are done to prepare drawing parameters. At the fifth level, the picture must be represented as a list of graphics figures drawable by the GDC. Finally, this representation must be manipulated, stored and communicated. The GDC takes care of the high-speed and repetitive tasks required to implement graphics systems.

GENERAL OVERVIEW

In order to minimize system bus loading, the 82720 uses a private video memory for storage of the video image. Up to 512K bytes of video memory can be directly supported. For example, this is sufficient capacity to store a 2048 x 2048 pixel x 1 bit image. Images can be generated on the screen by:

- Drawing Commands
- Program-Controlled Transfers
- DMA Transfers from System Memory

The 82720 can be configured to support a wide variety of graphics applications. It can support:

- High Dot Rates
- Color Planes
- Horizontal Split Screen
- Character-oriented Displays
- Multiplexed Graphic and Character Display

GRAPHIC DISPLAY CONFIGURATIONS

The 82720 provides the flexibility to handle a wide variety of graphic applications. This flexibility results from having its own private video memory for storage of the graphics image. The organization of this memory determines the performance, the number of bits/pixel and the size of the display. Several different video memory organizations are examined in the following paragraphs.

In the simplest 82720 system, the memory can store up to a 2048 x 2048 x 1 bit image. It can display a 1024 x 1024 x 1 bit section of the image at a maximum dot rate of 44 MHz, or 88 MHz in wide mode. In this configuration, only 1 bit/pixel is used.

By partitioning the memory into multiple banks, color, gray scale and higher bandwidth displays can be supported. By adding various amounts of external logic, many cost/performance tradeoffs for both display and drawing are realizable.

The video memory can be partitioned into 4 banks, each 1024 x 1024 bits. By selecting all 4 memory banks during display, 4 bits/pixel can be provided by a single 82720. Each bank of video memory contributes 1 bit to each pixel. This configuration can support color monitors, again with a maximum dot shift rate of 44 or 88 MHz.

Higher performance may be achieved by using multiple 82720s. Multiple 82720s can be used to support multiple display windows, increased drawing speed, or increased bits per pixel. For display windows, each 82720 controls one window of the display. For increased drawing speed, multiple 82720s are operated in parallel. For increased bits/pixel, each 82720 contributes a portion of the number of bits necessary for a pixel.

CHARACTER DISPLAY CONFIGURATION

Although the 82720 is intended primarily for raster-scan graphics, it can be used as a character display controller. The 82720 can support up to 8K by 13 bits of private video memory in this configuration (1 character = 13 bits). This is sufficient memory to store 4 screens of data containing 25 rows by 80 characters. The 82720 can display up to 256 characters per row. Smooth vertical scrolling of each of 4 independent display partitions is also supported.

MIXED DISPLAY CONFIGURATION

The GDC can support a mixed display system for both graphic and character information. This capability allows the display screen to be partitioned between graphic and character data. It is possible to switch between one graphic display window and one character display window with raster line resolution. A maximum of 256K bytes of video memory is supported in this mode: half is for graphic data, half is for character data. In graphic mode, a one megapixel image can be stored and displayed. In character mode, 64K, 18-bit characters can be stored.

DETAILED OPERATIONAL DESCRIPTION

The GDC can be used in one of three basic modes —Graphics Mode, Character Mode and Mixed Mode. This section of the data sheet describes the following for each mode:

1. Memory organization
2. Display timing
3. Special Display functions
4. Drawing and writing
Graphics Mode Memory Organization

The Display Memory is organized into 16-bit words (32-bit words in wide mode). Since the display memory can be larger than the CRT display itself, two width parameters must be specified: display memory width and display width. The Display width (in words) is selected by a parameter of the Reset command. The Display memory width (in words) is selected by a parameter of the Pitch command. The height of the Display memory can be larger than the display itself. The height of the Display is selected by a parameter of the Reset command. The GDC can directly address up to 4Mbits (0.5Mbytes) of display RAM in graphics mode.

Graphics Mode Display Timing

All raster blanking and display timings of the GDC are a function of the input clock frequency. Sixteen or 32 bits of data are read from the RAM and loaded into a shift register in each two clock period display cycle. The Address and Data busses of the GDC are multiplexed. In the first part of the cycle, the address of the word to be read is latched into an external demultiplexer. In the second part of the cycle, the data is read from the RAM and loaded into the shift register. Since all 16 (32) bits of data are to be displayed, the dot clock is \(8 \times (16 \times)\) the GDC clock or \(16 \times (32 \times)\) the Read cycle rate.

Parameters of the Reset or Sync command determine the horizontal and vertical front porch, sync pulse, and back porch timings. Horizontal parameters are specified as multiples of the display cycle time, and vertical parameters as a multiple of the line time.

Another Reset command parameter selects interlaced or non-interlaced mode. A bit in the parameter RAM can define Wide Display Mode. In this mode, while data is being sent to the screen, the display address counter is incremented by two rather than one. This allows the display memory to be configured to deliver 32 bits from each display read cycle.

The V Sync command specifies whether the V Sync Pin is an input or an output. If the V Sync Pin is an output, the GDC generates the raster timing for the display and other CRT controllers can be synchronized to it. If the V Sync pin is an input, the GDC can be synchronized to any external vertical Sync signal.

Graphics Mode Special Display Functions:

**WINDOWING**
The GDC’s Graphics Mode Display can be divided into two windows on the screen, upper and lower. The windows are defined by parameters written into the GDC’s parameter RAM. Each window is specified by a starting address and a window length in lines. If the second window is not used, the first window parameters should be specified to be the same as the active display length.

**ZOOMING**
A parameter of the GDC’s zoom command allows zooming by effectively increasing the size of the dots on the screen. This is accomplished vertically by repeating the same display line. The number of times it is repeated is determined by the display zoom factor parameter. Horizontally, zoom is accomplished by extending each display word cycle and displaying fewer words per line, according to the zoom factor. It is the responsibility of the microprocessor controlling the GDC to provide the shift register clock circuitry with the zoom factor required to slow down the shift registers to the appropriate speed. The frequency of the 2WCLK should not be changed. The zoom factor must be set to a known state upon initialization.

**PANNING**
Panning is accomplished by changing the starting address of the display window. In this way, panning is possible in any direction, vertically on a line by line basis and horizontally on a word by word basis.

Graphics Mode Drawing and Writing

The GDC can draw solid or patterned lines, arcs, circles, rectangles, slanted rectangles, characters, slanted characters, filled rectangles. Direct access to the bit map is also provided via the DMA Commands and the Read or Write data commands.

MEMORY MODIFICATION

All drawing and writing functions take place at the location in the display RAM specified by the cursor. The cursor is not displayed in Graphics Mode. The cursor location is modified by the execution of drawing, reading or writing commands. The cursor will move to the bit following the last bit accessed.
Each bit is drawn by executing a Read-Modify-Write cycle on the display RAM. These R/M/W cycles normally require four 2xWCLK cycles to execute. If the display zoom factor is greater than two, each R/M/W cycle will be extended to the width of a display cycle. Write Data (WDAT), Read Data (RDAT), DMA write (DMAW) and DMA read (DMAR) commands can be used to examine or modify one to 16 bits in each word during each R/M/W cycle. All other graphics drawing commands modify one bit per R/M/W cycle.

An internal 16-bit Mask register determines which bit(s) in the accessed word are to be modified. A one in the Mask register allows the corresponding bit in the display RAM to be modified by the R/M/W cycle. A zero in the Mask register prevents the GDC from modifying the corresponding bit in the display RAM.

The mask must be set by the Mask Command prior to issuing the WDAT or DMAW command. The Mask register is automatically set by the CURS command and manipulated by the graphics commands.

The display RAM bits can be modified in one of four ways. They can be set to 1, reset to 0, complemented or replaced by a pattern.

When replace by a pattern mode is selected, lines, arcs and rectangles will be drawn using the 16-bit pattern in parameter RAM bytes 8 and 9.

In set, reset, or complement mode, parameter RAM bytes 8 and 9 act as another level of masking for line arc and rectangle drawing. As each 16-bit segment of the line or arc is drawn, it is checked against the pattern in the parameter RAM. If the pattern RAM bit is a one, the display RAM bit will be set, reset, or complemented per the proper modes. If the pattern RAM bit is a zero, the display RAM bit won't be modified.

When replace by pattern mode is selected, the graphics character and fill commands will cause the 8 x 8 pattern in parameter RAM bytes 8 to 15 to be written directly into the display RAM in the appropriate locations.

In set, reset, or complement mode, the 8 x 8 pattern in parameter RAM bytes 8 to 15 act as a mask pattern for graphics character or fill commands. If the appropriate parameter RAM bit is set, the display RAM bit will be modified. If the parameter RAM bit is zero, the display RAM bit will not be modified. These modes are selected by issuing a WDAT command without parameters before issuing graphics commands. The pattern in the parameter RAM has no effect on WDAT, RDAT, DMAW, or DMAR operations.

**READING AND DRAWING COMMANDS**

After the modification mode has been set and the parameter RAM has been loaded, the final drawing parameters are loaded via the figure specify (FIGS) command. The first parameter specifies the direction in which drawing will occur and the figure type to be drawn. This parameter is followed by one to five more parameters depending on the type of character to be drawn.

The direction parameter specifies one of eight octants in which the drawing or reading will occur. The effect of drawing direction on the various figure types is shown in Figure 9.

RDAT, WDAT, DMAW, and DMAR Operations move through the Display memory as shown in the "DMA" Column.

The other parameters required to set up figure reading or drawing are shown in Figure 3.

- D = DRAWING COUNT PARAMETER WHICH IS ONE LESS THAN THE NUMBER OF R/W CYCLES TO BE EXECUTED.
- D = DOTS MASKED FROM DRAWING DURING ARC DRAWING.
- D = NECESSARY ONLY FOR WORD READS.

---

Figure 3. Drawing Parameter Details
After the parameters have been set, line, arc, circle, rectangle or slanted rectangle drawing operations are initiated by the Figure Draw (FIGD) command. Character, slanted character, area fill and slanted area fill drawing operations are initiated by the Graphics Character Draw (GCHR) command. DMA transfers are initiated by the DMA Read or Write (DMAR or DMAW) commands. Data Read Operations are initiated by the Read Data (RDAT) Command. Data Write Operations are initiated by writing a parameter after the WDAT command.

The area fill operation steps and repeats the 8 x 8 graphics character pattern draw operation to fill a rectangular area. If the size of the rectangle is not an integral number of 8 x 8 pixels, the GDC will automatically truncate the pattern at the edges furthest from the starting point.

The Graphics Character Drawing capability can be modified by the Graphics Character Write Zoom Factor (GCHW) parameter of the zoom command. The zoom write factor may be set from 1 to 16 (by using from 0 to 15 in the parameter). Each dot will be repeated in memory horizontally and vertically (adjusted for drawing direction) the number of times specified by the zoom factor.

The WDAt command can be used to rapidly fill large areas in memory with the same value. The mask is set to all 1's, and the least significant bit of the WDAt parameter replaces all bits of each word written.

Character Mode Memory Organization

In character mode, the Display memory is organized into up to 8K characters of up to 13 bits each. Wide mode is also available for characters of up to 26 bits.

The display memory can be larger than the display itself. The display width (in characters) is a parameter of the reset command. The display width (in characters) is a parameter of the Pitch Command. The height of the display (in lines) is a parameter of the Reset Command. The display memory height is determined by dividing the number of display memory words by the pitch.

In character mode, the display works almost exactly as it does in graphics mode. The differences lie in the fact that data read from the display RAM is used to drive a character generator as well as attribute logic if desired. In Character mode, address bits 13-18 become line counter outputs used to select the proper line of the character generator, and the address 17 output becomes the cursor and line counter MSB output.

Character Mode Display Timing

In character mode, the display timing works as it does in graphics mode: In addition, the Address 17 output becomes cursor output. The characteristics of the cursor are defined by parameters of the cursor and Character Characteristics (CUR) command. One bit allows the cursor output to be enabled or disabled. The height of the cursor is programmable by selecting the top and bottom line of which the cursor will appear. The blink rate is also programmable. The parameter selects the number of frame times that the cursor will be inactive and active, resulting in a 50% duty cycle cursor blinking at 2 x the period specified by the parameter.

The cursor output pin also provides the line counter bit 4 signal, which is valid 10 clocks after the trailing edge of HSYNC.

Character Mode Special Display Functions

WINDOWING

The GDC's Character Mode display can be partitioned into one to four windows on the screen. The windows are defined by parameters written into the GDC's Parameter RAM. Each window is specified by a starting address and a window length in lines.

If windowing is not required, the first window length should be specified to be the same as the active display length.

ZOOMING AND PANNING

In character mode, zooming and pan handling commands function the same way as in Graphics Mode.

Character Mode Drawing and Writing

The GDC can read or write characters of up to 13 bits into or out of the Display RAM.

All reading and writing functions take place at the display RAM location specified by the cursor. The cursor location can be read by issuing the CURD command. The cursor can be moved anywhere within the display memory by the CURS command. The cursor location is also modified by the execution of character read or write commands.

Each character is written or read via a Read/Modify/Write cycle. The mask register contents determine which bit(s) in the character are modified. The mask register can be used to change character codes without modifying attribute bits or vice-versa. The Replace with pattern, Set, Reset and Complement

Mixing Modes

In mixing modes, two memory spaces are used in which the content of each page of an MDC is maintained in a separate memory space.

The contents of the Memory Page Command can also be presented in a one-to-one format. The Memory Page Command is defined by the MIX command, which can be set to control the mixing of memory spaces.

In character mode, the Mix command allows the mixing of memory spaces to be controlled.

Simple Mix

In mixing modes, the mixing of memory spaces is controlled by the MIX command. The MIX command can be used to select the memory space to be used for a particular memory read or write operation. The MIX command is defined by the MIX command, which can be set to control the mixing of memory spaces.

In this mode, the MIX command allows the mixing of memory spaces to be controlled.

Simple Mix

In mixing modes, the mixing of memory spaces is controlled by the MIX command. The MIX command can be used to select the memory space to be used for a particular memory read or write operation. The MIX command is defined by the MIX command, which can be set to control the mixing of memory spaces.

In this mode, the MIX command allows the mixing of memory spaces to be controlled.
modes work exactly as they do in graphics mode, with the exception that the parameter RAM Pattern is not used. The pattern used is a parameter of the WDAT command.

The Figure Specify (FIGS) command must be set to Character Display mode, as well as specify the direction the cursor will be moved by read or write data commands.

In character mode, the FIGD and GCHRD commands are not used.

Mixed Mode Memory Organization

In mixed mode, the display memory is organized into two banks of up to 64K words of 16 bits each (32 bits in wide mode).

The display height and width are programmable by the same Reset or Sync command parameters as in the graphics and character modes. The display memory width (in words) is a parameter of the Pitch Command and the height of the display memory is determined by dividing the number of display memory words by the pitch.

An image mode signal is used to switch the external circuitry between graphics and character modes in two display windows.

In a graphics window, the GDC works as does in pure graphics mode, but on a smaller total memory space (64K words vs 512K words).

In a character window, the GDC works as it does in pure character mode, but the line counter must be implemented externally. The counter is clocked by the horizontal sync pulse and reset by a signal supplied by the GDC.

In mixed mode, the GDC provides both a cursor and an attribute blink timing signal.

Mixed Mode Display Timing

In mixed mode, each word in a graphic area is accessed twice in succession. The AW parameter of the Reset or Sync command should be set to twice its normal value, and the video shift register load signal must be suppressed during the extra access cycle.

In addition, A16 becomes a Multiplexed Attribute and Clear Line Counter signal and A17 becomes a multiplexed cursor and image mode signal. A16 provides an active high line counter reset signal which is valid 10 clocks after the trailing edge of HSYNC. During the active display line time, A16 provides blink timing for external attribute circuitry. This signal blinks at 1/2 the blink rate of the cursor with a 75% on, 25% off duty cycle. A17 provides a signal which selects between graphics or character display, which is also valid 10 clocks after the trailing edge of HSYNC. During the active display time, A17 provides the cursor signal. The cursor timing and characteristics are defined in exactly the same way as in pure character mode.

Mixed Mode Special Display Functions

WINDOWING
The GDC supports two display windows in mixed mode. They can independently be programmed into either graphics or character mode determined by the state of two bits in the parameter RAM. The window location in display memory and size are also determined by parameters in the parameter RAM.

ZOOMING AND PANNING
In mixed mode, zooming and panning commands function the same as in graphics and character mode.

Mixed Mode Drawing and Writing
In mixed mode, the GDC can write or draw in exactly the same ways as in both graphics and character modes. In addition, the FIGS command has a parameter GD (Graphics Drawing Flag) which sets the image mode signal to select the proper RAM bank.

DEVICE PROGRAMMING

The GDC occupies two addresses on the system microprocessor bus through which the GDC's status register and FIFO are accessed. Commands and parameters are written into the GDC FIFO and are differentiated by address bit A0. The status register or the FIFO can be read as selected by the address line.

Figure 4. GDC Microprocessor Bus Interface Registers
Commands to the GDC take the form of a command byte followed by a series of parameter bytes as needed for specifying the details of the command. The command processor decodes the commands, unpacks the parameters, loads them into the appropriate registers within the GDC and initiates the required operations.

The commands available in the GDC can be organized into five categories as described in figure 5.

**VIDEO CONTROL COMMANDS**
1. **RESET**: Resets the GDC to its idle state.
2. **SYNC**: Specifies the video display format.
3. **VSYNC**: Selects master or slave video synchronization mode.
4. **CDHAR**: Specifies the cursor and character row heights.

**DISPLAY CONTROL COMMANDS**
1. **START**: Ends idle mode and unblanks the display.
2. **BCTR**: Controls the blanking and unblanking of the display.
3. **ZOOM**: Specifies zoom factors for the display and coordinates the display with the graphics character writing.
4. **CURS**: Sets the position of the cursor in display memory.
5. **PRAM**: Defines starting addresses and lengths of display areas and specifies the right byte for the graphics character.
6. **PITCH**: Specifies the width of the x dimension of display memory.

**DRAWING CONTROL COMMANDS**
1. **WDAT**: Writes data words or bytes to display memory.
2. **MARK**: Sets the mark register contents.
3. **FIGS**: Specifies the parameters for the drawing process.
4. **FIGD**: Draws the figure as specified above.
5. **GRCHD**: Draws the graphics character into display memory.

**MEMORY DATA READ COMMANDS**
1. **RDAT**: Reads data words or bytes from display memory.
2. **CURR**: Reads the cursor position.
3. **LPNL**: Reads the light pen address.
4. **DMA CONTROL COMMANDS**
   - **DMAR**: Requests a DMA read transfer.
   - **DWMN**: Requests a DMA write transfer.

**FIFO Operation & Command Protocol**

The first-in, first-out buffer (FIFO) in the GDC handles the command dialogue with the system microprocessor. This flow of information uses a half-duplex technique, in which the single 16-byte FIFO is used for both directions of data movement, one direction at a time. The FIFO’s direction is controlled by the system microprocessor through the GDC’s command set. The microprocessor coordinates these transfers by checking the appropriate status register bits.

The command protocol used by the GDC requires the differentiation of the first byte of a command sequence from the succeeding bytes. This first byte contains the operation code and the remaining bytes carry parameters. Writing into the GDC causes the FIFO to store a flag value alongside the data byte to signify whether the byte was written into the command or the parameter address. The command processor in the GDC tests this bit as it interprets the entries in the FIFO.
The receipt of a command byte by the command processor marks the end of any previous operation. The number of parameter bytes supplied with a command is cut short by the receipt of the next command byte. A read operation from the GDC to the microprocessor can be terminated at any time by the next command.

The FIFO changes direction under the control of the system microprocessor. Commands written into the GDC always put the FIFO into write mode if it wasn't in it already. If it was in read mode, any read data in the FIFO at the time of the turnaround is lost. Commands which require a GDC response, such as RDAT, CURD and LPRD, put the FIFO into read mode after the command is interpreted by the GDC's command processor. Any commands and parameters behind the read-evoking command are discarded when the FIFO direction is reversed.

Read-Modify-Write Cycle

Data transfers between the GDC and the display memory are accomplished using a read-modify-write (RMW) memory cycle. The four clock period timing of the RMW cycle is used to: 1) output the address, 2) read data from the memory, 3) modify the data, and 4) write the modified data back into the initially selected memory address. This type of memory cycle is used for all interactions with display memory including DMA transfers, except for the two clock period display and RAM refresh cycles.

The operations performed during the modify portion of the RMW cycle merit additional explanation. The circuitry in the GDC uses three main elements: the Pattern register, the Mask register, and the 16-bit Logic unit. The Pattern register holds the data pattern to be moved into memory. It is loaded by the WDAT command or, during drawing, from the parameter RAM. The Mask register contents determine which bits of the read data will be modified. Based on the contents of these registers, the Logic unit performs the selected operations of REPLACE, COMPLEMENT, SET, or CLEAR on the data read from display memory.

The Pattern register contents are ANDed with the Mask register contents to enable the actual modification of the memory read data, on a bit-by-bit basis. For graphics drawing, one bit at a time from the Pattern register is combined with the Mask. When ANDed with the bit set to a 1 in the Mask register, the proper single pixel is modified by the Logic Unit. For the next pixel in the figure, the next bit in the Pattern register is selected and the Mask register bit is moved to identify the pixel's location within the word. The Execution word address pointer register, EAD, is also adjusted as required to address the word containing the next pixel.

In character mode, all of the bits in the Pattern register are used in parallel to form the respective bits of the modify data word. Since the bits of the character code word are used in parallel, unlike the one-bit-at-a-time graphics drawing process, this facility allows any or all of the bits in a memory word to be modified in one RMW memory cycle. The Mask register must be loaded with 1s in the positions where modification is to be permitted.

The Mask register can be loaded in either of two ways. In graphics mode, the CURS command contains a four-bit dAD field to specify the dot address. The command processor converts this parameter into the one-of-16 format used in the Mask register for figure drawing. A full 16 bits can be loaded into the Mask register using the MASK command. In addition to the character mode use mentioned above, the 16-bit MASK load is convenient in graphics mode when all of the pixels of a word are to be set to the same value.

The Logic unit combines the data read from display memory, the Pattern register, and the Mask register to generate the data to be written back into display memory. Any one of four operations can be selected: REPLACE, COMPLEMENT, CLEAR or SET. In each case, if the respective Mask bit is 0, that particular bit of the read data is returned to memory unmodified. If the Mask bit is 1, the modification is enabled. With the REPLACE operation, the modify data simply takes the place of the read data for modification enabled bits. For the other three operations, a 0 in the modify data allows the read data bit to be returned to memory. A 1 value causes the specified operation to be performed in the bit positions with set Mask bits.

Figure Drawing

The GDC draws graphics figures at the rate of one pixel per read-modify-write (RMW) display memory cycle. These cycles take four clock periods to complete. At a clock frequency of 5 MHz, this is equal to 800 ns. During the RMW cycle the GDC simultaneously calculates the address and position of the next pixel to be drawn.

The graphics figure drawing process depends on the display memory addressing structure. Groups of 16 horizontally adjacent pixels form the 16-bit words
which are handled by the GDC. Display memory is organized as a linearly addressed space of these words. Addressing of individual pixels is handled by the GDC's internal RMW logic.

During the drawing process, the GDC finds the next pixel of the figure which is one of the eight nearest neighbors of the last pixel drawn. The GDC assigns each of these eight directions a number from 0 to 7, starting with straight down and proceeding counterclockwise.

Figure 7. Drawing Directions

Figure drawing requires the proper manipulation of the address and the pixel bit position according to the drawing direction to determine the next pixel of the figure. To move to the word above or below the current one, it is necessary to subtract or add the number of words per line in display memory. This parameter is called the pitch. To move to the word to either side, the Execute word address cursor, EAD, must be incremented or decremented as the dot address pointer bit reaches the LSB or the MSB of the Mask register. To move to a pixel within the same word, it is necessary to rotate the dot address pointer register to the right or left.

Figure 8 summarizes these operations for each direction.

Whole word drawing is useful for filling areas in memory with a single value. By setting the Mask register to all 1s with the Mask command, both the LSB and MSB of the dAD will always be 1, so that the EAD value will be incremented or decremented for each cycle regardless of direction. One RMW cycle will be able to affect all 16 bits of the word for any drawing type. One bit in the Pattern register is used per RMW cycle to write all the bits of the word to the same value. The next Pattern bit is used for the word, etc.

Figure 8. Address Calculation Details
For the various figures, the effect of the initial direction upon the resulting drawing is shown in Figure 9.

Note that during line drawing, the angle of the line may be anywhere within the shaded octant defined by the DIR value. Arc drawing starts in the direction initially specified by the DIR value and veers into an arc as drawing proceeds. An arc may be up to 45 degrees in length. DMA transfers are done on word boundaries only, and follow the arrows indicated in the table to find successive word addresses. The slanted paths for DMA transfers indicate the GDC changing both the X and Y components of the word address when moving to the next word. It does not follow a 45 degree diagonal path by pixels.

Figure 9. Effect of the Direction Parameter
Drawing Parameters

In preparation for graphics figure drawing, the GDC's Drawing Processor needs the figure type, direction and drawing parameters, the starting pixel address, and the pattern from the microprocessor. Once these are in place within the GDC, the Figure Draw command, FIGD, initiates the drawing operation. From that point on, the system microprocessor is not involved in the drawing process. The GDC Drawing Processor coordinates the RMW circuitry and address registers to draw the specified figure pixel by pixel.

The algorithms used by the processor for figure drawing are designed to optimize its drawing speed. To this end, the specific details about the figure to be drawn are reduced by the microprocessor to a form conducive to high-speed address calculations within the GDC. In this way, the repetitive, pixel-by-pixel calculations can be done quickly, thereby minimizing the overall figure drawing time. Figure 3 summarizes the parameters.

Graphics Character Drawing

Graphics characters can be drawn into display memory pixel-by-pixel. The up to 8-by-8 character is loaded into the GDC's parameter RAM by the system microprocessor. Consequently, there are no limitations on the character set used. By varying the drawing parameters and drawing direction, numerous drawing options are available. In area fill applications, a character can be written into display memory as many times as desired without reloading the parameter RAM.

Once the parameter RAM has been loaded with up to eight graphics character bytes by the appropriate PRAM command, the GCHRD command can be used to draw the bytes into display memory starting at the cursor. The zoom magnification factor for writing, set by the zoom command, controls the size of the character written into the display memory in integral multiples of 1 through 16. The bit values in the PRAM are repeated horizontally and vertically the number of times specified by the zoom factor.

The movement of these PRAM bytes to the display memory is controlled by the parameters of the FIGS command. Based on the specified height and width of the area to be drawn, the parameter RAM is scanned to fill the required area.

For an 8-by-8 graphics character, the first pixel drawn uses the LSB of RA-15, the second pixel uses bit 1 of RA-15, and so on, until the MSB of RA-15 is reached. The GDC jumps to the corresponding bit in RA-14 to continue the drawing. The progression then advances toward the LSB of RA-14. This scanning sequence is continued for the other 8 PRAM bytes. This progression matches the sequence of display memory addresses calculated by the drawing processor as shown in figure 9. If the area is narrower than 8 pixels wide, the scanning will advance to the next PRAM byte before the MSB is reached. If the area is less than 8 lines high, fewer bytes in the parameter RAM will be scanned. If the area is larger than 8 by 8, the GDC will repeat the contents of the parameter RAM in two dimensions.
Parameter RAM Contents

The parameters stored in the parameter RAM, PRAM, are available for the GDC to refer to repeatedly during figure drawing and raster-scanning. In each mode of operation the values in the PRAM are interpreted by the GDC in a predetermined fashion. The host microprocessor must load the appropriate parameters into the proper PRAM locations. PRAM loading command allows the host to write into any location of the PRAM and transfer as many bytes as desired. In this way any stored parameter byte or bytes may be changed without influencing the other bytes.

The PRAM stores two types of information. For specifying the details of the display area partitions, blocks of four bytes are used. The four parameters stored in each block include the starting address in display memory of each display area, and its length.

In addition, there are two mode bits for each area which specify whether the area is a bit-mapped graphics area or a coded character area, and whether a normal or wide display cycle is to be used for that area.

The other use for the PRAM contents is to supply the pattern for figure drawing when in a bit-mapped graphics area or mode. In these situations, PRAM bytes 8 through 16 are reserved for this patterning information. For line, arc, and rectangle drawing (linear figures) locations 8 and 9 are loaded into the Pattern register to allow the GDC to draw dotted, dashed, etc. lines. For area filling and graphics bit-mapped character drawing locations 8 through 15 are referenced for the pattern or character to be drawn.

Details of the bit assignments are shown on the following pages for the various modes of operation.
Figure 10. Parameter RAM Contents—Character Mode
Figure 11. Parameter RAM Contents—Graphics and Mixed Graphics and Character Modes
### Video Control Commands

#### Figure 13. Reset Command

**RESET COMMAND**

This command can be executed at any time and does not modify any of the parameters already loaded into the GDC.

If followed by parameter bytes, this command also sets the sync generator parameters as described below. Idle mode is exited with the START command.
In graphics mode, a word is a group of 16 pixels. In character mode, a word is one character code and its attributes, if any.

The number of active words per line must be an even number from 2 to 256.

An all-zero parameter value selects a count equal to $2^n$ where $n =$ number of bits in the parameter field for vertical parameters.

All horizontal widths are counted in display words. All vertical intervals are counted in lines.

### Sync Parameter Constraints

#### HORIZONTAL FRONT PORCH CONSTRAINTS

1. In general:
   
   HFP $\geq 2$ words

2. If DMA is used, or the display zoom factor is greater than one in interlaced display mode:
   
   HFP $\geq 3$ words

3. If the GDC is used in slave mode:
   
   HFP $\geq 4$ words

4. If the light pen input is used:
   
   HFP $\geq 6$ words

#### HORIZONTAL Sync CONSTRAINTS

1. If dynamic RAM refresh is used:
   
   HS $\geq 2$ words

2. If interlaced display mode is used:
   
   HS $\geq 5$ words

#### HORIZONTAL BACK PORCH CONSTRAINTS

1. In general:
   
   HBP $\geq 3$ words

2. If interlaced display mode is used, or the IMAGE or WIDE mode bits change within one video field:
   
   HBP $\geq 5$ words

### MODE CONTROL BITS (FIGURE 15)

<td>Description</td>
<td>2 Field Sequence with $\frac{1}{2}$ line offset between otherwise identical fields.</td>
<td>2 Field Sequence with $\frac{1}{2}$ line offset. Each field displays alternate lines.</td>
<td>1 field brings all of the information to the screen.</td>
</tr>
</tbody>
</table>

Total scanned lines in interlace mode is odd. The sum of VFP + VS + VBP + AL should equal one less than the desired odd number of lines.

Dynamic RAM refresh is important when high display zoom factors or DMA are used in such a way that not all of the rows in the RAMs are regularly accessed during display raster generation and for otherwise inactive display memory.

Access to display memory can be limited to retrace blanking intervals only, so that no disruptions of the image are seen on the screen.

SYNC Format Specify Command

This command loads parameters into the sync generator. The various parameter fields and bits are identical to those at the RESET command. The GDC is not reset nor does it enter idle mode.

Vertical Sync Mode Command

When using two or more GDCs to contribute to one image, one GDC is defined as the master sync generator, and the others operate as its slaves. The VSYNC pins of all GDCs are connected together.

Slave Mode Operation

A few considerations should be observed when synchronizing two or more GDCs to generate overlayed video via the VSYNC INPUT/OUTPUT pin. As mentioned above, the Horizontal Front Porch (HFP) must be 4 or more display cycles wide. This is equivalent to eight or more clock cycles. This gives the slave GDCs time to initialize their internal video sync generators to the proper point in the video field to match the incoming vertical sync pulse (VSYNC). This resetting of the generator occurs just after the end of the incoming VSYNC pulse, during the HFP interval. Enough time during HFP is required to allow the slave GDC to complete the operation before the start of the HSYNC interval.

Once the GDCs are initialized and set up as Master and Slaves, they must be given time to synchronize. It is a good idea to watch the VSYNC status bit of the Master GDC and wait until after one or more VSYNC pulses have been generated before the display process is started. The START command will begin the active display of data and will end the video synchronization process, so be sure there has been at least one VSYNC pulse generated for the Slaves to synchronize to.

---

**Figure 17. Vertical Sync Mode Command**

**Figure 18. Cursor & Character Characteristics Command**
Cursor and Character Characteristics Command

In graphics mode, LR should be set to 0. For interfaced displays in graphics mode, BR should be set to 3. The blink rate parameter controls both the cursor and attribute blink rates. The cursor blink-on-time = blink-off-time = 2 x BR (video frames). The attribute blink rate is always \( \frac{1}{2} \) the cursor rate but with a \( \frac{3}{4} \) on-\( \frac{3}{4} \) off duty cycle.

DISPLAY CONTROL COMMANDS

Zoom Factors Specify Command

Zoom magnification factors of 1 through 16 are available using codes 0 through 15, respectively.

Cursor Position Specify Command

In character mode, the third parameter byte is not needed. The cursor is displayed for the word time in which the display scan address (DAD) equals the cursor address. In graphics mode, the cursor word address specifies the word containing the starting pixel of the drawing; the dot address value specifies the pixel within that word.

Parameter RAM Load Command

From the starting address, SA, any number of bytes may be loaded into the parameter RAM at incrementing addresses, up to location 15. The sequence of parameter bytes is terminated by the next command byte entered into the FIFO. The parameter RAM stores 16 bytes of information in predefined locations which differ for graphics and character modes. See the parameter RAM discussion for bit assignments.

Pitch Specification Command

This value is used during drawing by the drawing processor to find the word directly above or below the current word, and during display to find the start of the next line.

The Pitch parameter (width of display memory) is set by two different commands. In addition to the PITCH command, the RESET (or SYNC) command also sets the pitch value. The "active words per line" parameter, which specifies the width of the raster scan display, also sets the Pitch of the display memory. In situations in which these two values are equal there is no need to execute a PITCH command.

![Table of Display Control Commands](image-url)

**Figure 19. Display Control Commands**
In graphics bit-map situations, only the LSB of the WDAT parameter bytes is used as the pattern in the RMW operations. Therefore it is possible to have only an all ones or all zeros pattern. In coded character applications all the bits of the WDAT parameters are used to establish the drawing pattern.

The WDAT command operates differently from the other commands which initiate RMW cycle activity. It requires parameters to set up the Pattern register while the other commands use the stored values in the parameter RAM. Like all of these commands, the

**DRAWING CONTROL COMMANDS**

**Write Data Command**

Upon receiving a set of parameters (two bytes for a word transfer, one for a byte transfer), one RMW cycle into Video Memory is done at the address pointed to by the cursor EAD. The EAD pointer is advanced to the next word, according to the previously specified direction. More parameters can then be accepted.

For byte writes, the unspecified byte is treated as all zeros during the RMW memory cycle.
WDAT command must be preceded by a FIGS command and its parameters. Only the first three parameters need to be given following the FIGS opcode, to set up the type of drawing, the DIR direction, and the DC value. The DC parameter +1 will be the number of RMW cycles done by the GDC with the first set of WDAT parameters. Additional sets of WDAT parameters will see a DC value of 0 which will cause only one RMW cycle to be executed.

**Figure 23. Mask Register Load Command**

**Figure 24. Figure Drawing Parameters Specify Command**
Mask Register Load Command

This command sets the value of the 16-bit Mask register of the figure drawing processor. The Mask register controls which bits can be modified in the display memory during a read-modify-write cycle.

The Mask register is loaded both by the MASK command and the third parameter byte of the CURS command. The MASK command accepts two parameter bytes to load a 16-bit value into the MASK register. All 16 bits can be individually one or zero, under program control. The CURS command on the other hand, puts a '1 of 16' pattern into the Mask register based on the value of the Dot Address value, dAD. If normal single-pixel-at-a-time graphics figure drawing is desired, there is no need to do a MASK command at all since the CURS command will set up the proper pattern to address the proper pixels as drawing progresses. For coded character DMA, and screen setting and clearing operations using the WDAT command, the MASK command should be used after the CURS command if its third parameter byte has been output. The Mask register should be set to all ones for any 'word-at-a-time' operation.

Figure Draw Start Command

On execution of this instruction, the GDC loads the parameters from the parameter RAM into the drawing processor and starts the drawing process at the pixel pointed to by the cursor, EAD, and the dot address, dAD.

Graphics Char. Draw and Area Fill Start Command

Based on parameters loaded with the FIGS command, this command initiates the drawing of the graphics character or area filling pattern stored in Parameter RAM. Drawing begins at the address in display memory pointed to by the EAD and dAD values.

DATA READ COMMANDS

Read Data Command

Using the DIR and DC parameters of the FIGS command to establish direction and transfer count, multiple RMW cycles can be executed without specification of the cursor address after the initial load (DC = number of words or bytes).

As this instruction begins to execute, the FIFO buffer direction is reversed so that the data read from display memory can pass to the microprocessor. Any commands or parameters in the FIFO at this time will be lost. A command byte sent to the GDC will immediately reverse the buffer direction back to write mode, and all RDAT information not yet read from the FIFO will be lost. MOD should be set to 00.

Cursor Address Read Command

The Execute Address, EAD, points to the display memory word containing the pixel to be addressed.

The Dot Address, dAD, within the word is represented as a 1-of-16 code.

Light Pen Address Read Command

The light pen address, LAD, corresponds to the display word address, DAD, at which the light pen input signal is detected and deglitched.

Figure 27. Read Data from Display Memory Command
**Figure 28. Cursor Address Read Command**

```
CLUD: 1,1,5,6,0,0,0

The following bytes are returned by the DDC:

1. A7, LAD, AB: Execute Address (EAD), Low Byte
2. A8, LAD, AB: Execute Address (EAD), Middle Byte
3. X, X, X, X, X, LAD: Execute Address (EAD), High Byte
4. LAD, AB: Dot Address (EAD), Low Byte
5. X, X, X, LAD: Dot Address (EAD), High Byte

X = Undefined
```

**Figure 29. Light Pen Address Read Command**

```
LPRD: 1,1,5,6,0,0,0

The following bytes are returned by the DDC:

1. A7, LAD, AB: Light Pen Address, Low Byte
2. A8, LAD, AB: Light Pen Address, Middle Byte
3. X, X, X, LAD, AB: Light Pen Address, High Byte

X = Undefined
```

**ABSOLUTE MAXIMUM RATINGS**

- Ambient Temperature Under Bias: 0°C to 70°C
- Storage Temperature: -65°C to 150°C
- Voltage on any Pin with Respect to Ground: -0.5V to +7V
- Power Dissipation: 1.5 Watt

*COMMENT: Exposing the device to stresses above those listed in Absolute Maximum Ratings could cause permanent damage. The device is not meant to be operated under conditions outside the limits described in the operational sections of this specification. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.*
